

## Chapter 486

# Equivalence Tests for Two Means in a Cluster-Randomized Design

---

### Introduction

This procedure computes power and sample size for Schuirmann's (1987) two one-sided (TOST) test of equivalence when the data come from a cluster-randomized design in which the outcome is a continuous normal random variable. Only a brief introduction to the subject of equivalence testing will be given here. For a comprehensive discussion, refer to Chow and Liu (1999).

It should be noted that we could not find any published results about equivalence testing in cluster-randomized designs. What we could find were Schuirmann's TOST procedure and a discussion of how to adjust the t-test sample size results given by Campbell and Walters (2014). So, we applied the Campbell and Walters adjustment to Schuirmann's test. We look forward to results that substantiate our approach.

Cluster-randomized designs are those in which whole clusters of subjects (classes, hospitals, communities, etc.) are put into the treatment group or the control group. In this case, the means of two groups, made up of  $K_i$  clusters of  $M_{ij}$  individuals each, are to be tested. Generally speaking, the larger the cluster sizes and the higher the correlation among subjects within the same cluster, the larger will be the overall sample size necessary to detect an effect with the same power.

---

### The Statistical Hypotheses

PASS follows the *two one-sided tests* approach described by Schuirmann (1987) and Phillips (1990). Remember that when testing equivalence, the null and alternative hypotheses are defined as follows.

$$H_0: \delta \leq EL \text{ or } \delta \geq EU \text{ versus } H_a: EL < \delta < EU$$

Rejecting  $H_0$  in favor of  $H_a$  infers that the group means are equivalent.

This test is called an *upper-tailed test* because it is rejected in samples in which the difference between the sample means is larger than  $D$ .

## Technical Details

Our formulation is a combination of equivalence formulas of Chow and Liu (199) and the cluster-randomized design formulas given in Campbell and Walters (2014) and Ahn, Heo, and Zhang (2015). Denote an observation by  $Y_{ijk}$  where  $i = 1, 2$  gives the group,  $j = 1, 2, \dots, K_i$  gives the cluster within group  $i$ , and  $k = 1, 2, \dots, m_{ij}$  denotes an individual in cluster  $j$  of group  $i$ .

We let  $\sigma^2$  denote the variance of  $Y_{ijk}$ , which is  $\sigma_{Between}^2 + \sigma_{Within}^2$ , where  $\sigma_{Between}^2$  is the variation between clusters and  $\sigma_{Within}^2$  is the variation within clusters. Also, let  $\rho$  denote the intraclass correlation coefficient (ICC) which is  $\sigma_{Between}^2 / (\sigma_{Between}^2 + \sigma_{Within}^2)$ . This correlation is the simply correlation between any two observations in the same cluster.

For sample size calculation, we assume that the  $m_{ij}$  are distributed with a mean cluster size of  $M_i$  and a coefficient of variation cluster sizes of  $COV$ . The variance of the two group means,  $\bar{Y}_i$ , are approximated by

$$V_i = \frac{\sigma^2(DE_i)(RE_i)}{K_i M_i}$$

$$DE_i = 1 + (M_i - 1)\rho$$

$$RE_i = \frac{1}{1 - (COV)^2 \lambda_i (1 - \lambda_i)}$$

$$\lambda_i = M_i \rho / (M_i \rho + 1 - \rho)$$

DE is called the *Design Effect* and RE is the *Relative Efficiency* of unequal to equal cluster sizes. Both are greater than or equal to one, so both inflate the variance.

Assume that  $\delta = \mu_1 - \mu_2$  is to be tested using two modified two-sample t-tests. The test statistics are

$$t_L = \frac{\bar{Y}_1 - \bar{Y}_2 - EL}{\sqrt{\hat{V}_1 + \hat{V}_2}}$$

and

$$t_U = \frac{\bar{Y}_1 - \bar{Y}_2 - EU}{\sqrt{\hat{V}_1 + \hat{V}_2}}$$

We assume these statistics have approximate t distributions with degrees of freedom  $DF = K_1 M_1 + K_2 M_2 - 2$  for a *subject-level* analysis or  $K_1 + K_2 - 2$  for a *cluster-level* analysis.

Define the noncentrality parameters as

$$\Delta_L = (\delta - EL) / \sigma_d$$

and

$$\Delta_U = (\delta - EU) / \sigma_d$$

where

$$\sigma_d = \sqrt{V_1 + V_2}.$$

The power of this test procedure is given by

$$\text{Power} = \Pr(T_L \geq t_{1-\alpha, DF} \text{ and } T_U \leq -t_{1-\alpha, DF})$$

where  $T_L$  and  $T_U$  are distributed as the bivariate, noncentral  $t$  distribution with noncentrality parameters  $\Delta_L$  and  $\Delta_U$ .

---

## Procedure Options

This section describes the options that are specific to this procedure. These are located on the Design tab. For more information about the options of other tabs, go to the Procedure Window chapter.

---

### Design Tab

The Design tab contains most of the parameters and options that you will be concerned with.

---

#### Solve For

##### Solve For

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are  $\delta$ , *Power*, *KI*, and *MI*.

Under most situations, you will select either *Power* to calculate power or *KI* to calculate the number of clusters. Occasionally, you may want to fix the number of clusters and find the necessary cluster size.

Note that the value selected here always appears as the vertical axis on the charts.

The program is set up to calculate power directly. To find appropriate values of the other parameters, a binary search is made using an iterative procedure until an appropriate value is found.

---

#### Test

##### Test Statistic

Specify which t-test statistic you are going to use: a t-test based on the number of subjects or a t-test in which the cluster means are treated as subjects.

##### T-Test Based on Number of Subjects

This uses the methodology shown in the recent books by Campbell and Walters (2014) and Ahn, Heo, and Zhang (2015). In this case, power is based on a t-test in which the variance is inflated to adjust for the clustering and the degrees of freedom is based on to the number of subjects.

##### T-Test Based on Number of Clusters

This uses the original methodology of Donner and Klar (1996). In this case, power is based on a t-test in which the variance is also inflated to adjust for the clustering, but the degrees of freedom are based on the number of clusters. Donner and Klar ignored the impact of COV, so, if you want to match their results, you should set the COV to zero.

---

#### Power and Alpha

##### Power

This option specifies one or more values for power. Power is the probability of rejecting a false null hypothesis, and is equal to one minus Beta. Beta is the probability of a type-II error, which occurs when a false null hypothesis is not rejected.

Values must be between zero and one. Historically, the value of 0.80 (Beta = 0.20) was used for power. Now, 0.90 (Beta = 0.10) is also commonly used.

A single value may be entered or a range of values such as *0.8 to 0.95 by 0.05* may be entered.

If your only interest is in determining the appropriate sample size for a confidence interval, set power to 0.5.

## Equivalence Tests for Two Means in a Cluster-Randomized Design

### Alpha

This option specifies one or more values for the probability of a type-I error. A type-I error occurs when a true null hypothesis is rejected.

Values must be between zero and one. Usually, the value of 0.025 is used for alpha of one-sided test and this has become a standard.

You may enter a range of values such as *0.025 0.05 0.10* or *0.01 to 0.10 by 0.01*.

---

## Sample Size – Number of Clusters & Cluster Size

### Group 1 (Treatment)

#### K1 (Number of Clusters)

Enter a value (or range of values) for the number of clusters in the treatment group. You may enter a range of values such as *10 to 20 by 2*. The sample size for this group is equal to the number of clusters times the average cluster size.

#### M1 (Average Cluster Size)

This is the average number of subjects per cluster in group one. This value must be a positive number that is at least one. You can use a list of values such as *100 150 200*.

### Group 2 (Control)

#### K2 (Number of Clusters)

This is the number of clusters in group two. This value must be a positive number. The sample size for this group is equal to the number of clusters times the number of subjects per cluster.

If you simply want a multiple of the value for group one, you would enter the multiple followed by *K1*, with no blanks. If you want to use *K1* directly, you do not have to premultiply by *1*. For example, all of the following are valid entries: *10 K1 2K1 0.5K1 K1*.

You can use a list of values such as *10 20 30* or *K1 2K1 3K1*.

#### M2 (Average Cluster Size)

This is the average number of subjects per cluster in group two. This value must be at least one.

If you simply want a multiple of the value for group one, you would enter the multiple followed by *M1*, with no blanks. If you want to use *M1* directly, you do not have to premultiply by *1*. For example, all of the following are valid entries: *10M1 2M1 0.5M1 M1*.

You can use a list of values such as *10 20 30* or *M1 2M1 3M1*.

## Coefficient of Variation of Cluster Sizes

### COV of Cluster Sizes

Enter the *coefficient of variation* of the cluster sizes (number of subjects). This value must be zero or a positive number. The COV of X is defined as the standard deviation of X divided by the mean of X.

Campbell and Walters (2014) page 71 give guidance on the possible values of COV. They indicate that as the average cluster size increases, COV tends toward 0.65. They say that typical values of COV range from 0.4 to 0.9.

You can use a list of values such as *0.4 0.6 0.8*.

## Equivalence Tests for Two Means in a Cluster-Randomized Design

### Standard Deviation

The standard deviation, calculated by the sample formula (divide by  $n-1$ ), is a measure of the variability. When no other information is available, Campbell and Walters (2014) page 71 suggest using  $(\text{Maximum Cluster Size} - \text{Minimum Cluster Size}) / 4$ .

### All Cluster Sizes Equal

When all cluster sizes are equal, the coefficient of variation is zero.

---

### Effect Size

#### |EU| (Upper Equivalence Limit)

Enter a value for the upper limit of equivalence. Differences greater than this value are not considered to be equivalent.

We use the absolute value brackets to emphasize that this value must be positive. The bounds of equivalence are from EL to EU.

#### Range

This value must be a positive value greater than  $\delta$ .

#### -|EL| (Lower Equivalence Limit)

Enter a value for the lower limit of equivalence. Differences less than this value are not considered to be equivalent. The bounds of equivalence are from EL to EU.

If you want symmetric limits, enter '-UPPER LIMIT' here to cause  $EL = -|EU|$ .

#### Range

This value must be a negative value less than  $\delta$ . You can enter a positive value, but it will be made negative by applying the transformation  $Y = -|X|$ .

#### $\delta$ (Mean Difference = $\mu_1 - \mu_2$ )

This is the actual difference between the treatment group mean and the reference group mean.

Usually, this value is set to zero for equivalence tests. However, you may use any value between EL and EU.

#### $\sigma$ (Standard Deviation)

Enter the subject-to-subject standard deviation. This standard deviation applies for both groups.

Note that  $\sigma$  must be a positive number. You can enter a single value such as 5 or a series of values such as 1 3 5 7 9 or 1 to 9 by 2.

Press the small ' $\sigma$ ' button to the right to obtain calculation options for estimating the standard deviation.

#### $\rho$ (Intracluster Correlation, ICC)

This is the value of the intracluster correlation coefficient. It may be interpreted as the correlation between any two observations in the same cluster. It may also be thought of as the proportion of the variation in response that can be accounted for by the between-cluster variation.

Possible values are from 0 to just below 1. Typical values are between 0.0001 and 0.05.

You may enter a single value or a list of values.

## Equivalence Tests for Two Means in a Cluster-Randomized Design

## Example 1 – Calculating Power

Suppose an equivalence test is to be conducted on data obtained from a cluster-randomized design in which  $EU=1$ ;  $EL = -\text{Upper Limit}$ ;  $\delta = 0$ ;  $\sigma = 2$ ;  $\rho = 0.02$ ;  $M1$  and  $M2 = 5, 10$ ;  $COV = 0.65$ ;  $alpha = 0.025$ ; and  $K1$  and  $K2 = 5, 10, 15$ , and  $20$ .

### Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Equivalence Test for Two Means in a Cluster-Randomized Design** procedure window by expanding **Means**, then **Two Independent Means**, then clicking on **Cluster-Randomized**, and then clicking on **Equivalence Test for Two Means in a Cluster-Randomized Design**. You may then make the appropriate entries as listed below, or open **Example 1** by going to the **File** menu and choosing **Open Example Template**.

### Report Definitions

- Power is the probability of rejecting a false null hypothesis. It should be close to one.
- $N_1$  and  $N_2$  are the number of subjects in groups 1 and 2, respectively.
- $K_1$  and  $K_2$  are the number of clusters in groups 1 and 2, respectively.
- $M_1$  and  $M_2$  are the average number of subjects per cluster in groups 1 and 2, respectively.
- EL is the lower equivalence limit. It is the lower bound on the interval of equivalence. Differences outside EL to EU are not equivalent.
- EU is the upper equivalence limit. It is the upper bound on the interval of equivalence. Differences outside EL to EU are not equivalent.
- COV is the coefficient of variation of the cluster sizes.
- $\delta$  is the mean difference ( $\mu_1 - \mu_2$ ) in the response at which the power is calculated.
- $\sigma$  is the standard deviation of the subject responses.
- $\rho$  (ICC) is the intraclass correlation.
- Alpha is the probability of rejecting a true null hypothesis, that is, rejecting when the means are actually equal.

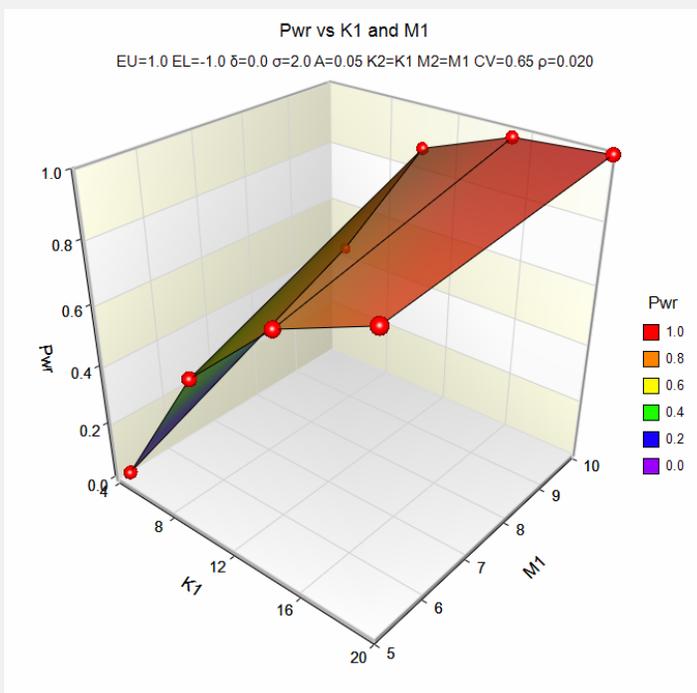

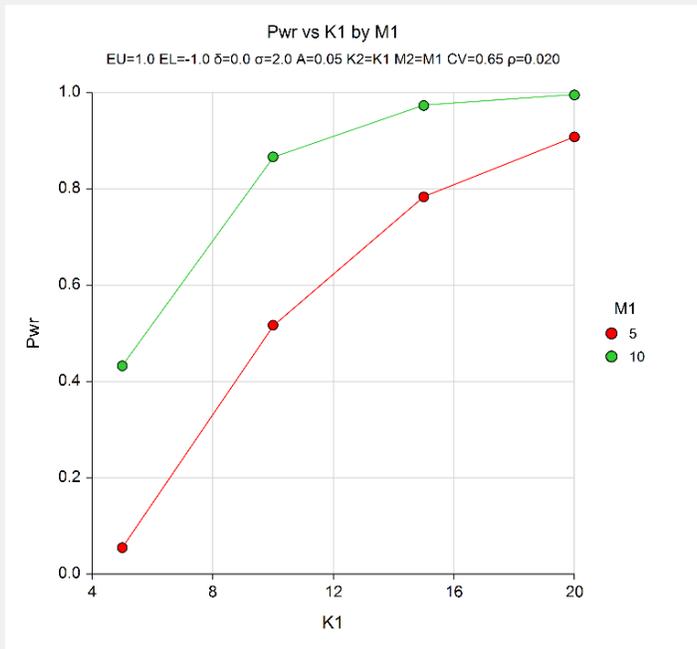

### Summary Statements

An equivalence test of means using two one-sided tests on data from a cluster-randomized design is to be conducted. Sample sizes of 25 in group one and 25 in group two, which were obtained by sampling 5 clusters with an average of 5 subjects each in group one and 5 clusters with an average of 5 subjects each in group two, achieve 5% power to detect equivalence. The interval of equivalence is between -1.0 and 1.0. The true difference between the means is assumed to be 0.0. The standard deviation of subjects is 2.0. The intraclass correlation coefficient is 0.020. The coefficient of variation of cluster sizes is 0.650. The significance level of the testing procedure is set at 0.050.

This report shows the power for each of the scenarios.

Equivalence Tests for Two Means in a Cluster-Randomized Design

Plots Section

These plots show the results of the various scenarios specified.

## Example 2 – Validation using Another PASS Procedure

We could not find a validation example for this procedure, so we will compare the results with the validation example of the *Equivalence Tests for Two Means using Differences* procedure. The results should be identical when  $M1 = M2 = 1$ . Use the following scenario: find  $K1$  when  $\delta = -2$ ,  $EU = 5$ ,  $EL = -5$ ,  $\sigma = 8$ ,  $\alpha = 0.05$ , and  $\text{power} = 0.80$ . That procedure obtained a validated value of 89 for  $K1$  and  $K2$ .

Because  $M1 = 1$ , the values of  $\rho$  and  $COV$  are set to 0.

### Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Equivalence Test for Two Means in a Cluster-Randomized Design** procedure window by expanding **Means**, then **Two Independent Means**, then clicking on **Cluster-Randomized**, and then clicking on **Equivalence Test for Two Means in a Cluster-Randomized Design**.
