

Chapter 802

Pearson's Correlation Tests (Simulation)

Introduction

This procedure analyzes the power and significance level of the Pearson Product-Moment Correlation Coefficient significance test using Monte Carlo simulation. This test is used to test whether the correlation is equal to a specified value. For each scenario that is set up, two simulations are run. One simulation estimates the significance level and the other estimates the power.

The Pearson correlation coefficient, ρ (rho), is a popular statistic for describing the strength of the relationship between two variables. It is the slope of the regression line between two variables when both variables have been standardized by subtracting their means and dividing by their standard deviations. The correlation ranges between plus and minus one. The population correlation ρ is estimated by the sample correlation coefficient r .

When ρ is used as a descriptive statistic, no special distributional assumptions need to be made about the variables (Y and X) from which it is calculated. When hypothesis tests are made, you assume that the observations are independent and that the variables are distributed according to the bivariate-normal density function. However, as with the t-test, tests based on the correlation coefficient are robust to moderate departures from this normality assumption.

Difference between Linear Regression and Correlation

The correlation coefficient is used when both X and Y are normally distributed (in fact, the assumption actually is that X and Y follow a bivariate normal distribution). In the linear regression context, no statement is made about the distribution of X. In fact, X is not even a random variable. Instead, it is a set of fixed values such as 10, 20, 30 or -1, 0, 1. Because of this difference in definition, we have included both Linear Regression and Correlation algorithms. This module deals with the Correlation (random X) case.

Technical Details

Computer simulation allows us to estimate the power and significance level that is actually achieved by a test procedure in situations that are not mathematically tractable. Computer simulation was once limited to mainframe computers. But, in recent years, as computer speeds have increased, simulation studies can be completed on desktop and laptop computers in a reasonable period of time.

The steps to a simulation study are

1. Specify the test procedure and the test statistic. This includes the significance level, sample size, and underlying data distributions.
2. Generate a random sample of points (X, Y) from the bivariate distribution specified by the alternative hypothesis. Calculate the test statistic from the simulated data and determine if the null hypothesis is

Pearson's Correlation Tests (Simulation)

accepted or rejected. These samples are used to calculate the power of the test. In the case of paired data, the individual values are simulated or constructed so that they exhibit the specified amount of correlation.

3. Generate a second random sample of points (X, Y) from the bivariate distribution specified by the null hypothesis. Calculate the test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. These samples are used to calculate the significance-level of the test. In the case of paired data, the individual values are simulated so that they exhibit the specified amount of correlation.
4. Repeat steps 2 and 3 several thousand times, tabulating the number of times the simulated data leads to a rejection of the null hypothesis. The power is the proportion of simulated samples in step 2 that lead to rejection. The significance level is the proportion of simulated samples in step 3 that lead to rejection.

Simulating Paired Distributions

In this routine, paired data may be generated from the bivariate normal distribution or from two specified marginal distributions. In the latter case, the simulation should mimic the actual data generation process as closely as possible, including the marginal distributions and the correlation between the two variables.

Obtaining paired samples from arbitrary distributions with a set correlation is difficult because the joint, bivariate distribution must be specified and simulated. Rather than specify the bivariate distribution, *PASS* requires the specification of the two marginal distributions and the correlation between them.

Monte Carlo samples with given marginal distributions and correlation are generated using the method suggested by Gentle (1998). The method begins by generating a large population of random numbers from the two distributions. Each of these populations is evaluated to determine if their means are within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean.

The next step is to obtain the target correlation. This is accomplished by permuting one of the populations until they have the desired correlation.

The above steps provide a large pool (ten thousand to one million items) of random number pairs that exhibit the desired characteristics. This pool is then sampled at random using the uniform distribution to obtain the random number pairs used in the simulation.

This algorithm may be stated as follows.

1. Draw individual samples of size M from the two distributions where M is a large number over 10,000. Adjust these samples so that they have the specified mean and standard deviation. Label these samples A and B. Create an index of the values of A and B according to the order in which they are generated. Thus, the first value of A and the first value of B are indexed as one, the second values of A and B are indexed as two, and so on up to the final set which is indexed as M.
2. Compute the correlation between the two generated variates.
3. If the computed correlation is within a small tolerance (usually less than 0.001) of the specified correlation, go to step 7.
4. Select two indices (I and J) at random using uniform random numbers.
5. Determine what will happen to the correlation if B_I is swapped with B_J . If the swap will result in a correlation that is closer to the target value, swap the indices and proceed to step 6. Otherwise, go to step 4.
6. If the computed correlation is within the desired tolerance of the target correlation, go to step 7. Otherwise, go to step 4.
7. End with a population with the required marginal distributions and correlation.

Pearson's Correlation Tests (Simulation)

A population created by this procedure tends to exhibit more variation in the tails of the distribution than in the center. Hence, the results using the bivariate normal option will be slightly different from those obtained when a custom model with two normal distributions is used.

Test Statistic

This section describes the test statistic that is used.

Sample Pearson Product-Moment Correlation Coefficient

The Pearson product-moment correlation coefficient is calculated from a sample of N data pairs (X, Y) using

$$r = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2 \sum(Y - \bar{Y})^2}}$$

The distribution of r assuming X and Y follow the bivariate normal distribution is known and available in *PASS*. It can be used to determine critical values for r .

Test Procedure

The testing procedure is as follows. H_0 is the null hypothesis that the true correlation is a specific value, ρ_0 (usually, $\rho_0 = 0$). H_1 represents the alternative hypothesis that the actual correlation of the population is ρ_1 , which is not equal to ρ_0 . Choose a value r_α , based on the distribution of the sample correlation coefficient, so that the probability of rejecting H_0 when H_0 is true is equal to a specified value, α .

Select a sample of N items from the population and compute the sample correlation coefficient, r_s . If $r_s > r_\alpha$ reject the null hypothesis that $\rho = \rho_0$ in favor of an alternative hypothesis that $\rho = \rho_1$, where $\rho_1 > \rho_0$. The power is the probability of rejecting H_0 when the true correlation is ρ_1 .

All calculations are based on the algorithm described by Guenther (1977) for calculating the cumulative correlation coefficient distribution.

Procedure Options

This section describes the options that are specific to this procedure. These are located on the Design tab. For more information about the options of other tabs, go to the Procedure Window chapter.

Design Tab

The Design tab contains most of the parameters and options that you will be concerned with.

Solve For

Solve For

This option specifies whether you want to solve for sample size or power.

Select *Sample Size* when you want to determine the sample size needed to achieve a given power and alpha error level.

Select *Power* when you want to calculate the power for a given power.

Pearson's Correlation Tests (Simulation)

Hypothesis and Simulations
Alternative Hypothesis

This option specifies the alternative hypothesis. This implicitly specifies the direction of the hypothesis test. The null hypothesis is $H_0: \rho_1 = \rho_0$.

Note that the alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- $\rho_1 \neq \rho_0$
This is the most common selection. It yields the *two-tailed* test. Use this option when you are testing whether the correlation values are different, but you do not want to specify beforehand which correlation is larger.
- $\rho_1 > \rho_0$
This option yields a *one-tailed* test.
- $\rho_1 < \rho_0$
This option also yields a *one-tailed* test.

Simulations

This option specifies the number of simulations, M . The larger the number of simulations, the longer the running time and the more accurate the results.

The precision of the simulated power estimates are calculated from the binomial distribution. Thus, confidence intervals may be constructed for various power values using the binomial distribution. The following table gives an estimate of the precision that is achieved for various simulation sizes when the power is either 0.50 or 0.95. The table values are interpreted as follows: a 95% confidence interval of the true power is given by the power reported by the simulation plus and minus the 'Precision' amount given in the table.

Simulation Size M	Precision when Power = 0.50	Precision when Power = 0.95
100	0.100	0.044
500	0.045	0.019
1000	0.032	0.014
2000	0.022	0.010
5000	0.014	0.006
10000	0.010	0.004
50000	0.004	0.002
100000	0.003	0.001

Notice that a simulation size of 1000 gives a precision of plus or minus 0.01 when the true power is 0.95. Also note that as the simulation size is increased beyond 5000, there is only a small amount of additional accuracy achieved.

Pearson's Correlation Tests (Simulation)

Power and Alpha (or Alpha)

Power

This option specifies one or more values for power. Power is the probability of rejecting a false null hypothesis, and is equal to one minus Beta. Beta is the probability of a type-II error, which occurs when a false null hypothesis is not rejected. In this procedure, a type-II error occurs when you fail to reject the null hypothesis of equal correlations when in fact they are different.

Values must be between zero and one. Historically, the value of 0.80 (Beta = 0.20) was used for power. Now, 0.90 (Beta = 0.10) is also commonly used.

A single value may be entered here or a range of values such as *0.8 to 0.95 by 0.05* may be entered.

Alpha

This option specifies one or more values for the probability of a type-I error. A type-I error occurs when you reject the null hypothesis of equal correlations when in fact they are equal.

Values of alpha must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

You may enter a range of values such as *0.01 0.05 0.10* or *0.01 to 0.10 by 0.01*.

Sample Size

N (Sample Size)

The number of observations in the sample. Each observation is made up of two values: one for X and one for Y .

Correlations

ρ_0 (Correlation|H0)

Specify the value of ρ_0 . Note that the range of the correlation is between plus and minus one. This value is usually set to zero.

ρ_1 (Correlation|H1)

Specify the value of ρ_1 , the population correlation under the alternative hypothesis. Note that the range of the correlation is between plus and minus one. The difference between ρ_0 and ρ_1 is being tested by this significance test.

You can enter a range of values separated by blanks or commas.

Power and Alpha Simulations

Distribution

Specify whether a bivariate normal or a custom bivariate distribution is used to generate the data. The possible choices are:

- **Bivariate Normal**

Bivariate normal distributions are simulated with zero means, unit variances, and correlations ρ_0 and ρ_1 to create the alpha and power simulations, respectively.

Pearson's Correlation Tests (Simulation)

- **Custom**

A bivariate distribution is specified by setting the two marginal distributions and their correlation (ρ_0 for the alpha simulation and ρ_1 for the power simulation).

The algorithm proceeds by generating a pool of several thousand random pairs from the X and Y distributions. To achieve the desired correlation, pairs of points are randomly selected and their X values are swapped if the switch results in an overall correlation closer to the desired value.

When applied to normal data, this algorithm results in a bivariate population that is narrower in the center and wider in the tails than the standard bivariate normal.

Custom Power and Alpha Distributions

These options specify the distributions of X and Y to be used in the power simulation (on the left) and the alpha simulation (on the right). All distributions are specified with the same syntax.

Distribution

Specify the distribution of each variable under the alternative hypothesis, H_1 , on the left and under the null hypothesis, H_0 , on the right.

For convenience in specifying a range of values, the parameters of a distribution can be specified using numbers or letters. If letters are used, their values are specified in the *Parameter Values* boxes below.

Following is a list of the distributions that are available and the syntax used to specify them. Each of the parameters should be replaced with a number or parameter name.

Distributions with Common Parameters

Beta(Shape1, Shape2, Min, Max)

Binomial(P,N)

Cauchy(Mean,Scale)

Constant(Value)

Exponential(Mean)

Gamma(Shape,Scale)

Gumbel(Location,Scale)

Laplace(Location,Scale)

Logistic(Location,Scale)

Lognormal(Mu,Sigma)

Multinomial(P1,P2,P3,...,Pk)

Normal(Mean,Sigma)

Poisson(Mean)

TukeyGH(Mu,S,G,H)

Uniform(Min, Max)

Weibull(Shape,Scale)

Pearson's Correlation Tests (Simulation)

Distributions with Mean and SD Parameters

BetaMS(Mean,SD,Min,Max)

BinomialMS(Mean,N)

GammaMS(Mean,SD)

GumbelMS(Mean,SD)

LaplaceMS(Mean,SD)

LogisticMS(Mean,SD)

LognormalMS(Mean,SD)

UniformMS(Mean,SD)

WeibullMS(Mean,SD)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on *Data Simulation* and will not be repeated here.

Power and Alpha Simulations – Parameter Values for X and Y Distributions

These options specify the names and values for the parameters used in the distributions.

Name

Up to five sets of named parameter values may be used in the simulation distributions. This option lets you select an appropriate name for each set of values. Possible names are

- **A to Z**

You might use these letters for location, shape, and scale parameters.

Value(s)

These values are substituted for the *Parameter Name* (M1, M2, SD, A, B, C, etc.) in the simulation distributions. If more than one value is entered, a separate calculation is made for each value.

You can enter a single value such as “2” or a series of values such as “0 2 3” or “0 to 3 by 1”.

Simulations Tab

The options on this tab controls the generation of the random numbers. For complicated distributions, a large pool of random numbers from the specified distributions is generated. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is at least the maximum of twice the number of simulated samples desired and 10,000.

Pearson's Correlation Tests (Simulation)

Random Numbers

Random Number Pool Size

This is the size of the pool of values from which the random samples will be drawn. Pools should be at least the minimum of 10,000 and twice the number of simulations. You can enter *Automatic* and an appropriate value will be calculated.

If you do not want to draw numbers from a pool, enter 0 here.

Correlation

Maximum Switches

This option specifies the maximum number of index switches that can be made while searching for a permutation of Y that yields a correlation within the specified tolerance.

A value near 5000000 is needed when the correlation is large.

Correlation Tolerance

Specify the amount above and below the target correlation that will still let a particular index-permutation to be selected as the bivariate population.

For example, if you have selected a correlation of 0.3 and you set this tolerance to 0.001, then permutations will continue until one is found which yields a correlation between 0.299 and 0.301.

Recommended: 0.001

Valid Values: 0 to 0.99.

Pearson's Correlation Tests (Simulation)

Example 1 – Finding the Power

Suppose a study will be run to test whether the correlation between forced vital capacity (X) and forced expiratory value (Y) in a particular population is non-zero. Find the power when $\rho_0 = 0$, $\rho_1 = 0.20$ and 0.30 , alpha is 0.05 , and $N = 20, 60, 100$.

Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Pearson's Correlation Tests (Simulation)** procedure window by expanding **Correlation**, then **Correlation**, then clicking on **Test (Inequality)**, and then clicking on **Pearson's Correlation Tests (Simulation)**. You may then make the appropriate entries as listed below, or open **Example 1** by going to the **File** menu and choosing **Open Example Template**.

Report Definitions

N is the size of the sample drawn from the population. It is the number of X-Y data points in a sample.
 Power is the probability of rejecting a false null hypothesis. It is calculated by the power simulation.
 ρ_0 is the Pearson correlation coefficient assuming the null hypothesis, H0. This is the value being tested.
 ρ_1 is the Pearson correlation coefficient assuming the alternative hypothesis, H1. This is the value at which the power is computed.
 Target Alpha is the probability of rejecting a true null hypothesis. It is set by the user.
 Actual Alpha is the alpha level that was actually achieved by the experiment. It is calculated by the alpha simulation.
 Beta is the probability of accepting a false null hypothesis.

Summary Statements

A sample size of 20 achieves 12% power to detect a difference of 0.200 between the null hypothesis Pearson correlation of 0.000 and the alternative hypothesis Pearson correlation of 0.200 using a two-sided hypothesis test with a significance level of 0.050. These results are based on 5000 Monte Carlo samples from the bivariate normal distribution under the alternative hypothesis.

Power and Alpha Confidence Intervals from Simulations

Row	Sample Size	Power	Lower Limit of 95% C.I. of Power	Upper Limit of 95% C.I. of Power	Target Alpha	Actual Alpha	Lower Limit of 95% C.I. of Alpha	Upper Limit of 95% C.I. of Alpha

Definitions of the Power and Alpha Confidence Intervals Report

N is the size of the sample drawn from the population. It is the number of X-Y data points in a sample.
 Power is the probability of rejecting H0 when it is false. This is the actual value calculated by the power simulation.
 Lower and Upper Limits of a 95% C.I. for Power are the limits of an exact, 95% confidence interval for power based on the binomial distribution. They are calculated from the power simulation.
 Target Alpha is the desired probability of rejecting a true null hypothesis at which the tests were run.
 Actual Alpha is the alpha achieved by the test as calculated by the alpha simulation.
 Lower and Upper Limits of a 95% C.I. for Alpha are the limits of an exact, 95% confidence interval for alpha based on the binomial distribution. They are calculated from the alpha simulation

The Numeric Results report gives the basic results. The Power and Alpha Confidence Intervals report provides a confidence interval for each power and alpha value that was simulated. Definitions follow the reports.

Pearson's Correlation Tests (Simulation)

Plots Section

This plot shows the relationship between power and sample size in this example.

Pearson's Correlation Tests (Simulation)

Example 2 – Finding the Sample Size

Continuing with the last example, find the sample size necessary to achieve a power of 90% with a 0.05 significance level.

Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Pearson's Correlation Tests (Simulation)** procedure window by expanding **Correlation**, then **Correlation**, then clicking on **Test (Inequality)**, and then clicking on **Pearson's Correlation Tests (Simulation)**. You may then make the appropriate entries as listed below, or open **Example 2** by going to the **File** menu and choosing **Open Example Template**.

<u>Option</u>	<u>Value</u>
Design Tab	
Solve For	Sample Size
Alternative Hypothesis	$\rho_1 \neq \rho_0$
Power	0.90
Alpha	0.05
ρ_0 (Correlation H0)	0.0
ρ_1 (Correlation H0)	0.2 0.3
Distribution	Bivariate Normal

Output

Click the Calculate button to perform the calculations and generate the following output.

Numeric Results

Simulation Summary							
Variables	Power (H1) Simulation Distribution	Alpha (H0) Simulation Distribution					
X and Y	Bivariate Normal	Bivariate Normal					
Random Number Pool Size	10000						
Number of Simulations	5000						
Numeric Results for Testing Correlation Hypotheses: H0: $\rho_1 = \rho_0$; H1: $\rho_1 \neq \rho_0$							
Row	Sample Size N	Target Power	Actual Power	H0 Corr ρ_0	H1 Corr ρ_1	Target Alpha	Actual Alpha
1	299	0.900	0.905	0.000	0.200	0.050	0.048
2	116	0.900	0.903	0.000	0.300	0.050	0.051

The required sample size is 299 for $\rho_1 = 0.2$ and 116 for $\rho_1 = 0.3$.

Pearson's Correlation Tests (Simulation)

Example 3 – Validation using Zar

Zar (1984) page 312 presents an example in which the power of a correlation coefficient is calculated. If $N = 12$, $\alpha = 0.05$, $\rho_0 = 0$, and $\rho_1 = 0.866$, Zar calculates a power of 98% for a two-sided test.

Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Pearson's Correlation Tests (Simulation)** procedure window by expanding **Correlation**, then **Correlation**, then clicking on **Test (Inequality)**, and then clicking on **Pearson's Correlation Tests (Simulation)**. You may then make the appropriate entries as listed below, or open **Example 3** by going to the **File** menu and choosing **Open Example Template**.

<u>Option</u>	<u>Value</u>
Design Tab	
Solve For	Power
Alternative Hypothesis	$\rho_1 \neq \rho_0$
Simulations	50000
Alpha	0.05
N (Sample Size)	12
ρ_0 (Correlation H0)	0.0
ρ_1 (Correlation H0)	0.866
Distribution	Bivariate Normal

Output

Click the Calculate button to perform the calculations and generate the following output.

Numeric Results

Numeric Results for Testing Correlation Hypotheses: H0: $\rho_1 = \rho_0$; H1: $\rho_1 \neq \rho_0$						
Row	Sample Size N	Power	H0 Corr ρ_0	H1 Corr ρ_1	Target Alpha	Actual Alpha
1	12	0.984	0.000	0.866	0.050	0.048

The power of 0.98 matches Zar's results.

Pearson's Correlation Tests (Simulation)

Example 4 – Validation using Graybill

Graybill (1961) pages 211-212 presents an example in which the power of a correlation coefficient is calculated when the baseline correlation is different from zero. Let $N = 24$, $alpha = 0.05$, and $\rho_0 = 0.5$. Graybill calculates the power of a two-sided test when $\rho_1 = 0.2$ and 0.3 to be 0.363 and 0.193 .

Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the **Pearson's Correlation Tests (Simulation)** procedure window by expanding **Correlation**, then **Correlation**, then clicking on **Test (Inequality)**, and then clicking on **Pearson's Correlation Tests (Simulation)**. You may then make the appropriate entries as listed below, or open **Example 4** by going to the **File** menu and choosing **Open Example Template**.

<u>Option</u>	<u>Value</u>
