About this manual

Congratulations on your purchase of the PASS package! PASS offers:

• Easy parameter entry.
• A comprehensive list of power analysis routines that are accurate and verified, yet are quick and easy to learn and use.
• Straightforward procedures for creating paper printouts and file copies of both the numerical and graphical reports.

Our goal is that with the help of these user's guides, you will be up and running on PASS quickly. After reading the quick start manual (at the front of User's Guide I) you will only need to refer to the chapters corresponding to the procedures you want to use. The discussion of each procedure includes one or more tutorials that will take you step-by-step through the tasks necessary to run the procedure.

I believe you will find that these user’s guides provides a quick, easy, efficient, and effective way for first-time PASS users to get up and running.

I look forward to any suggestions you have to improve the usefulness of this manual and/or the PASS system. Meanwhile, good computing!

Jerry Hintze, Author
PASS License Agreement

Important: The enclosed Power Analysis and Sample Size software program (PASS) is licensed by NCSS to customers for their use only on the terms set forth below. Purchasing the system indicates your acceptance of these terms.

1. **LICENSE.** NCSS hereby agrees to grant you a non-exclusive license to use the accompanying PASS program subject to the terms and restrictions set forth in this License Agreement.

2. **COPYRIGHT.** PASS and its documentation are copyrighted. You may not copy or otherwise reproduce any part of PASS or its documentation, except that you may load PASS into a computer as an essential step in executing it on the computer and make backup copies for your use on the same computer.

3. **BACKUP POLICY.** PASS may be backed up by you for your use on the same machine for which PASS was purchased.

4. **RESTRICTIONS ON USE AND TRANSFER.** The original and any backup copies of PASS and its documentation are to be used only in connection with a single user. This user may load PASS onto several machines for his/her convenience (such as a desktop and laptop computer), but only for use by the licensee. You may physically transfer PASS from one computer to another, provided that PASS is used in connection with only one user. You may not distribute copies of PASS or its documentation to others. You may transfer this license together with the original and all backup copies of PASS and its documentation, provided that the transferee agrees to be bound by the terms of this License Agreement. PASS licenses may not be transferred more frequently than once in twelve months. Neither PASS nor its documentation may be modified or translated without written permission from NCSS.

   You may not use, copy, modify, or transfer PASS, or any copy, modification, or merged portion, in whole or in part, except as expressly provided for in this license.

5. **NO WARRANTY OF PERFORMANCE.** NCSS does not and cannot warrant the performance or results that may be obtained by using PASS. Accordingly, PASS and its documentation are licensed "as is" without warranty as to their performance, merchantability, or fitness for any particular purpose. The entire risk as to the results and performance of PASS is assumed by you. Should PASS prove defective, you (and not NCSS or its dealer) assume the entire cost of all necessary servicing, repair, or correction.

6. **LIMITED WARRANTY ON CD.** To the original licensee only, NCSS warrants the medium on which PASS is recorded to be free from defects in materials and faulty workmanship under normal use and service for a period of ninety days from the date PASS is delivered. If, during this ninety-day period, a defect in a cd should occur, the cd may be returned to NCSS at its address, or to the dealer from which PASS was purchased, and PASS will replace the cd without charge to you, provided that you have sent a copy of your receipt for PASS. Your sole and exclusive remedy in the event of a defect is expressly limited to the replacement of the cd as provided above.

   Any implied warranties of merchantability and fitness for a particular purpose are limited in duration to a period of ninety (90) days from the date of delivery. If the failure of a cd has resulted from accident, abuse, or misapplication of the cd, NCSS shall have no responsibility to replace the cd under the terms of this limited warranty. This limited warranty gives you specific legal rights, and you may also have other rights which vary from state to state.

7. **LIMITATION OF LIABILITY.** Neither NCSS nor anyone else who has been involved in the creation, production, or delivery of PASS shall be liable for any direct, incidental, or consequential damages, such as, but not limited to, loss of anticipated profits or benefits, resulting from the use of PASS or arising out of any breach of any warranty. Some states do not allow the exclusion or limitation of direct, incidental, or consequential damages, so the above limitation may not apply to you.

8. **TERM.** The license is effective until terminated. You may terminate it at any time by destroying PASS and documentation together with all copies, modifications, and merged portions in any form. It will also terminate if you fail to comply with any term or condition of this License Agreement. You agree upon such termination to destroy PASS and documentation together with all copies, modifications, and merged portions in any form.
9. **YOUR USE OF PASS ACKNOWLEDGES** that you have read this customer license agreement and agree to its terms. You further agree that the license agreement is the complete and exclusive statement of the agreement between us and supersedes any proposal or prior agreement, oral or written, and any other communications between us relating to the subject matter of this agreement.

Dr. Jerry L. Hintze & NCSS, Kaysville, Utah

**Preface**

**PASS** (Power Analysis and Sample Size) is an advanced, easy-to-use statistical analysis software package. The system was designed and written by Dr. Jerry L. Hintze over the last fifteen years. Dr. Hintze drew upon his experience both in teaching statistics at the university level and in various types of statistical consulting.

The present version, written for 32-bit versions of Microsoft Windows (98, 2000, ME, NT, XP, etc.) computer systems, is the result of several iterations. Experience over the years with several different types of users has helped the program evolve into its present form.

NCSS maintains a website at WWW.NCSS.COM where we make the latest edition of **PASS** available for free downloading. The software is password protected, so only users with valid serial numbers may use this downloaded edition. We hope that you will download the latest edition routinely and thus avoid any bugs that have been corrected since you purchased your copy.

We believe **PASS** to be an accurate, exciting, easy-to-use program. If you find any portion which you feel needs to be changed, please let us know. Also, we openly welcome suggestions for additions and enhancements.

**Verification**

All calculations used in this program have been extensively tested and verified. First, they have been verified against the original journal article or textbook that contained the formulas. Second, they have been verified against second and third sources when these exist.

Chapter 550

One-Way ANOVA

Introduction

A common task in research is to compare the averages of two or more populations (groups). We might want to compare the income level of two regions, the nitrogen content of three lakes, or the effectiveness of four drugs. The one-way analysis of variance compares the means of two or more groups to determine if at least one mean is different from the others. The $F$ test is used to determine statistical significance. $F$ tests are nondirectional in that the null hypothesis specifies that all means are equal and the alternative hypothesis simply states that at least one mean is different.

The methods described here are usually applied to the one-way experimental design. This design is an extension of the design used for the two-sample $t$ test. Instead of two groups, there are three or more groups. With careful modifications, this procedure may be used to test interaction terms as well.

Planned Comparisons

$PASS$ performs power and sample size calculations for user-specified contrasts.

The usual $F$ test tests the hypothesis that all means are equal versus the alternative that at least one mean is different from the rest. Often, a more specific alternative is desired. For example, you might want to test whether the treatment means are different from the control mean, the low dose is different from the high dose, a linear trend exists across dose levels, and so on. These questions are tested using planned comparisons.

We call the comparison planned because it was determined before the experiment was conducted. We planned to test the comparison.

A comparison is a weighted average of the means, in which the weights may be negative. When the weights sum to zero, the comparison is called a contrast. $PASS$ provides results for contrasts. To specify a contrast, we need only specify the weights. Statisticians call these weights the contrast coefficients.

For example, suppose an experiment conducted to study a drug will have three dose levels: none (control), 20 mg., and 40 mg. The first question is whether the drug made a difference. If it did, the average response for the two groups receiving the drug should be different from the control. If we label the group means M0, M20, and M40, we are interested in comparing M0 with M20 and M40. This can be done in two ways. One way is to construct two tests, one comparing M0 and M20 and the other comparing M0 and M40. Another method is to perform one test comparing M0 with the average of M20 and M40. These tests are conducted using planned comparisons. The coefficients are as follows:
M0 vs. M20

To compare M0 versus M20, use the coefficients -1,1,0. When applied to the group means, these coefficients result in the comparison M0(-1)+M20(1)+M40(0) which reduces to M20-M0. That is, this contrast results in the difference between the two group means. We can test whether this difference is non-zero using the $t$ test (or $F$ test since the square of the $t$ test is an $F$ test).

M0 vs. M40

To compare M0 versus M40, use the coefficients -1,0,1. When applied to the group means, these coefficients result in the comparison M0(-1)+M20(0)+M40(1) which reduces to M40-M0. That is, this contrast results in the difference between the two group means.

M0 vs. Average of M20 and M40

To compare M0 versus the average of M20 and M40, use the coefficients -2,1,1. When applied to the group means, these coefficients result in the comparison M0(-2)+M20(1)+M40(1) which is equivalent to M40+M20-2(M0).

To see how these coefficients were obtained, consider the following manipulations. Beginning with the difference between the average of M20 and M40 and M0, we obtain the coefficients above—aside from a scale factor of one-half.

\[
\frac{M20 + M40}{2} - M0 = \frac{M20}{2} + \frac{M40}{2} - \frac{M0}{1}
\]

\[
= \frac{1}{2} M20 + \frac{1}{2} M40 - M0
\]

\[
= \frac{1}{2} (M20 + M40 - 2M0)
\]

Assumptions

Using the $F$ test requires certain assumptions. One reason for the popularity of the $F$ test is its robustness in the face of assumption violation. However, if an assumption is not even approximately met, the significance levels and the power of the $F$ test are invalidated. Unfortunately, in practice it often happens that several assumptions are not met. This makes matters even worse. Hence, steps should be taken to check the assumptions before important decisions are made.

The assumptions of the one-way analysis of variance are:

1. The data are continuous (not discrete).
2. The data follow the normal probability distribution. Each group is normally distributed about the group mean.
3. The variances of the populations are equal.
4. The groups are independent. There is no relationship among the individuals in one group as compared to another.
5. Each group is a simple random sample from its population. Each individual in the population has an equal probability of being selected in the sample.
**Technical Details for the One-Way AOV**

Suppose $k$ groups each have a normal distribution and equal means ($\mu_1 = \mu_2 = \cdots = \mu_k$). Let $n_1 = n_2 = \cdots = n_k$ denote the number of subjects in each group and let $N$ denote the total sample size of all groups. Let $\mu_w$ denote the weighted mean of all groups. That is

$$\mu_w = \sum_{i=1}^{k} \left( \frac{n_i}{N} \right) \mu_i$$

Let $\sigma$ denote the common standard deviation of all groups.

Given the above terminology, the ratio of the mean square between groups to the mean square within groups follows a central $F$ distribution with two parameters matching the degrees of freedom of the numerator mean square and the denominator mean square. When the null hypothesis of mean equality is rejected, the above ratio has a noncentral $F$ distribution which also depends on the noncentrality parameter, $\lambda$. This parameter is calculated as

$$\lambda = N \frac{\sigma_m^2}{\sigma^2}$$

where

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} n_i (\mu_i - \mu_w)^2}{N}}$$

Some authors use the symbol $\phi$ for the noncentrality parameter. The relationship between the two noncentrality parameters is

$$\phi = \frac{\sqrt{\lambda}}{k}.$$ 

The process of planning an experiment should include the following steps:

1. Determine an estimate of the within group standard deviation, $\sigma$. This may be done from prior studies, from experimentation with the Standard Deviation Estimation module, from pilot studies, or from crude estimates based on the range of the data. See the chapter on estimating the standard deviation for more details.

2. Determine a set of means that represent the group differences that you want to detect.

3. Determine the appropriate group sample sizes that will ensure desired levels of $\alpha$ and $\beta$.

Although it is tempting to set all group sample sizes equal, it is easy to show that putting more subjects in some groups than in others may have better power than keeping group sizes equal (see Example 4).
Power Calculations for One-Way AOV

The calculation of the power of a particular test proceeds as follows:

1. Determine the critical value, $F_{k-1, N-k, \alpha}$ where $\alpha$ is the probability of a type-I error and $k$ and $N$ are defined above. Note that this is a two-tailed test as no direction is assigned in the alternative hypothesis.

2. From a hypothesized set of $\mu_i$'s, calculate the noncentrality parameter $\lambda$ based on the values of $N, k, \sigma_m$, and $\sigma$.

3. Compute the power as the probability of being greater than $F_{k-1, N-k, \alpha}$ on a noncentral-$F$ distribution with noncentrality parameter $\lambda$.

Technical Details for a Planned Comparison

The terminology of planned comparisons is identical to that of the one-way AOV, so the notation used above will be repeated here.

Suppose you want to test whether the contrast $C$

$$C = \sum_{i=1}^{k} c_i \mu_i$$

is significantly different from zero. Here the $c_i$'s are the contrast coefficients.

Define

$$\sigma_{mc} = \sqrt{\frac{\sum_{i=1}^{k} c_i \mu_i}{N \sum_{i=1}^{k} \frac{c_i^2}{n_i}}}$$

Define the noncentrality parameter $\lambda_c$, as

$$\lambda_c = N \frac{\sigma_{mc}^2}{\sigma^2}$$
Power Calculations for Planned Comparisons

The calculation of the power of a particular test proceeds as follows:

1. Determine the critical value, $F_{1,N-k,\alpha}$ where $\alpha$ is the probability of a type-I error and $k$ and $N$ are defined above. Note that this is a two-tailed test as no direction is assigned in the alternative hypothesis.

2. From a hypothesized set of $\mu_i$'s, calculate the noncentrality parameter $\lambda_c$ based on the values of $N$, $k$, $\sigma_{mc}$, and $\sigma$.

3. Compute the power as the probability of being greater than $F_{1,N-k,\alpha}$ on a noncentral-$F$ distribution with noncentrality parameter $\lambda_c$.

Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are $SM$, $S$, $k$, $n$, Alpha, and Beta. Under most situations, you will select either Beta for a power analysis or $n$ for sample size determination.

$k$ (Number of Groups)

This is the number of group means being compared. It must be greater than or equal to two.

You can enter a list of values, in which case, a separate analysis will be calculated for each value. Commas or blanks may separate the numbers. A TO-BY list may be used.

Note that the number of items used in the Hypothesized Means box and the Group Sample Size Pattern box is controlled by this number.

Examples:

- 2,3,4
- 2 3 4
- 2 to 10 by 2
Hypothesized Means

Enter a set of hypothesized means, one for each group. These means represent the group centers under the alternative hypothesis (the null hypothesis is that they are equal). The standard deviation of these means ($\sigma_m$) is used in the power calculations to represent the average size of the differences among the means. The standard deviation of the means is calculated using the formula:

$$
\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (\mu_i - \overline{\mu})^2}{k}}
$$

This quantity gives the magnitude of the differences among the group means. Note that when all means are equal, $\sigma_m$ is zero.

You should enter a set of means that give the pattern of differences you expect or the pattern that you wish to detect. For example, in a particular study involving three groups, your research might be “meaningful” if either of two treatment means is 50% larger than the control mean. If the control mean is 50, then you would enter 50, 75, 75 as the three means.

It is usually more intuitive to enter a set of mean values. However, it is possible to enter the standard deviation of the means directly by placing an $S$ in front of the number (see below).

Some might wish to specify the alternative hypothesis as the effect size, $f$, which is defined as

$$
f = \frac{\sigma_m}{\sigma}
$$

If so, set $\sigma = 1$ and $\sigma_m = f$. Cohen (1988) has designated values of $f$ less than 0.1 as small, values around 0.25 to be medium, and values over 0.4 to be large.

Entering a list of means

If a set of numbers is entered without a leading $S$, they are assumed to be the hypothesized group means under the alternative hypothesis. Their standard deviation will be calculated and used in the calculations. Blanks or commas may separate the numbers. Note that it is not the values of the means themselves that is important, but only their differences. Thus, the mean values 0, 1, 2 produce the same results as the values 100, 101, 102.

If too few means are entered to match the number of groups, the last mean is repeated. For example, suppose that four means are needed and you enter 1, 2 (only two means). PASS will treat this as 1, 2, 2, 2. If too many values are entered, PASS will truncate the list to the number of means needed.

Examples:

5 20 60
2, 5, 7
-4, 0, 6, 9
S Option
If an S is entered before the list of numbers, they are assumed to be values of $\sigma_m$, the standard deviations of the group means. A separate power calculation is made for each value. Note that this list can be a TO-BY phrase.

Examples:
S 4.7
S 4.3 5.7 4.2
S 10 to 20 by 2

Contrast Coefficients
If you want to analyze a specific planned comparison, enter a set of contrast coefficients here. The calculations will then refer to the hypothesis that the corresponding contrast of the means is zero versus the alternative that it is non-zero (two-sided test). These are often called Planned Comparisons.

A contrast is a weighted average of the means in which the weights sum to zero. For example, suppose you are studying four groups and that the main hypothesis of interest is whether there is a linear trend across the groups. You would enter -3, -1, 1, 3 here. This would form the weighted average of the means:

$$-3(\text{Mean}_1) - (\text{Mean}_2) + (\text{Mean}_3) + 3(\text{Mean}_4)$$

The point to realize is that these numbers (the coefficients) are used to calculate a specific weighted average of the means which is to be compared against zero using a standard $F$ (or $t$) test.

NONE or blank
When the box is left blank or the word None is entered, this option is ignored.

Linear Trend
A set of coefficients is generated appropriate for testing the alternative hypothesis that there is a linear (straight-line) trend across the means. These coefficients assume that the means are equally spaced across the trend variable.

Quadratic
A set of coefficients is generated appropriate for testing the alternative hypothesis that the means follow a quadratic model. These coefficients assume that the means are equally spaced across the implicit $X$ variable.

Cubic
A set of coefficients is generated appropriate for testing the alternative hypothesis that the means follow a cubic model. These coefficients assume that the means are equally spaced across the implicit $X$ variable.

First Against Others
A set of coefficients is generated appropriate for testing the alternative hypothesis that the first mean is different from the average of the remaining means. For example, if there were four groups, the generated coefficients would be -3, 1, 1, 1.
**List of Coefficients**

A list of coefficients, separated by commas or blanks, may be entered. If the number of items in the list does not match the number of groups ($k$), zeros are added or extra coefficients are truncated.

Remember that these coefficients must sum to zero. Also, the scale of the coefficients does not matter. That is $0.5, 0.25, 0.25$; $-2, 1, 1$; and $-200, 100, 100$ will yield the same results.

To avoid rounding problems, it is better to use $-3, 1, 1, 1$ than the equivalent $-1, 0.333, 0.333, 0.333$. The second set does not sum to zero.

**n (Sample Size Multiplier)**

This is the base, per group, sample size. One or more values, separated by blanks or commas, may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number times each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by $m_1, m_2, m_3, \ldots, m_k$ and this value is represented by $n$, the group sample sizes $N_1, N_2, N_3, \ldots, N_k$ are calculated as follows:

$$N_1 = \lceil n(m_1) \rceil$$
$$N_2 = \lceil n(m_2) \rceil$$
$$N_3 = \lceil n(m_3) \rceil$$

etc.

where the operator, $\lceil \cdot \rceil$ means the next integer after $\cdot$, e.g. $\lceil 3.1 \rceil = 4$.

For example, suppose there are three groups and the Group Sample Size Pattern is set to $1, 2, 3$. If $n$ is 5, the resulting sample sizes will be 5, 10, and 15. If $n$ is 50, the resulting group sample sizes will be 50, 100, and 150. If $n$ is set to $2, 4, 6, 8, 10$; five sets of group sample sizes will be generated and an analysis run for each. These sets are:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>12</td>
</tr>
<tr>
<td>6</td>
<td>12</td>
<td>18</td>
</tr>
<tr>
<td>8</td>
<td>16</td>
<td>24</td>
</tr>
<tr>
<td>10</td>
<td>20</td>
<td>30</td>
</tr>
</tbody>
</table>
As a second example, suppose there are three groups and the Group Sample Size Pattern is 0.2, 0.3, 0.5. When the fractional Pattern values sum to one, \( n \) can be interpreted as the total sample size of all groups and the Pattern values as the proportion of the total in each group.

If \( n \) is 10, the three group sample sizes would be 2, 3, and 5.

If \( n \) is 20, the three group sample sizes would be 4, 6, and 10.

If \( n \) is 12, the three group sample sizes would be

\[(0.2)12 = 2.4\] which is rounded up to the next whole integer, 3.
\[(0.3)12 = 3.6\] which is rounded up to the next whole integer, 4.
\[(0.5)12 = 6.\]

Note that in this case, 3+4+6 does not equal \( n \) (which is 12). This can happen because of rounding.

**Group Sample Size Pattern**

A set of positive, numeric values, one for each group, is entered here. The sample size of group \( i \) is found by multiplying the \( i \)th number from this list times the value of \( n \) and rounding up to the next whole number. The number of values must match the number of groups, \( k \). When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

**Equal**

If all sample sizes are to be equal, enter “Equal” here and the desired sample size in \( n \). A set of \( k \) 1’s will be used. This will result in \( N1 = N2 = N3 = n \). That is, all sample sizes are equal to \( n \).

**Alpha**

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal means when in fact the means are equal.

Values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

**Beta**

This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal means when in fact the means are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.
S - Std Dev of Subjects

This is $\sigma$, the standard deviation within a group. It represents the variability from subject to subject that occurs when the subjects are treated identically. It is assumed to be the same for all groups. This value is approximated in an analysis of variance table by the square root of the mean square error.

Since they are positive square roots, the numbers must be strictly greater than zero. You can press the SD button to obtain further help on estimating the standard deviation.

Note that if you are using this procedure to test a factor (such as an interaction) from a more complex design, the value of standard deviation is estimated by the square root of the mean square of the term that is used as the denominator in the $F$ test.

You can enter a list of values separated by blanks or commas, in which case, a separate analysis will be calculated for each value.

Examples of valid entries:
1,4,7,10
1 4 7 10
1 to 10 by 3
Example 1 - Finding the Statistical Power

An experiment is being designed to compare the means of four groups using an $F$ test with a significance level of either 0.01 or 0.05. Previous studies have shown that the standard deviation within a group is 18. Treatment means of 40, 10, 10, and 10 represent clinically important treatment differences. To better understand the relationship between power and sample size, the researcher wants to compute the power for several group sample sizes between 2 and 14. The sample sizes will be equal across all groups.

#### Report Definitions

- **Power**: The probability of rejecting a false null hypothesis. It should be close to one.
- **Average n**: The average of the group sample sizes.
- **k**: The number of groups.
- **Total N**: The total sample size of the study.
- **Alpha**: The probability of rejecting a true null hypothesis. This is often called the significance level.
- **Beta**: The probability of accepting a false null hypothesis. It should be small.
- **Sm**: The standard deviation of the group means under the alternative hypothesis.
- **Standard deviation**: The within group standard deviation.
- **Effect Size**: The ratio of Sm to standard deviation.

#### Summary Statements

In a one-way ANOVA study, sample sizes of 2, 2, 2, and 2 are obtained from the 4 groups whose means are to be compared. The total sample of 8 subjects achieves 4% power to detect differences among the means versus the alternative of equal means using an F test with a 0.01000 significance level. The size of the variation in the means is represented by their standard deviation which is 12.99. The common standard deviation within a group is assumed to be 18.00.

This report shows the numeric results of this power study. Following are the definitions of the columns of the report.

**Power**

The probability of rejecting a false null hypothesis.

**Average n**

The average of the group sample sizes.

**k**

The number of groups.

**Total N**

The total sample size of the study.

**Alpha**

The probability of rejecting a true null hypothesis. This is often called the significance level.

**Beta**

The probability of accepting a false null hypothesis that Sm is zero when Sm is actually equal to the value shown in the next column.
**Std Dev of Means**
This is the standard deviation of the hypothesized means. It was computed from the hypothesized means. It is roughly equal to the average difference between the group means and the overall mean.

Once you have computed this, you can enter a range of values to determine the effect of the hypothesized means on the power.

**Standard Deviation (S)**
This is the within-group standard deviation. It was set in the Data window.

**Effect Size**
The effect size is the ratio of $SM$ to $S$. It is an index of relative difference between the means that can be compared from study to study.

<td></td>
</tr>
</tbody>
</table>

This report shows the details of each row of the previous report.

**Group**
The number of the group shown on this line. The last line, labeled **ALL**, gives the average or the total as appropriate.

**Ni**
This is the sample size of each group. This column is especially useful when the sample sizes are unequal.

**Percent Ni of Total Ni**
This is the percentage of the total sample that is allocated to each group.

**Mean**
The is the value of the Hypothesized Mean. The final row gives the average for all groups.

**Deviation From Mean**
This is the absolute value of the mean minus the overall mean. Since $Sm$ is the sum of the squared deviations, these values show the relative contribution to $Sm$. 
Ni Times Deviation
This is the group sample size times the absolute deviation. It shows the combined influence of the size of the deviation and the sample size on Sm.

Plot Section

This plot gives a visual presentation to the results in the Numeric Report. We can quickly see the impact on the power of increasing the sample size and increase the significance level.

When you create one of these plots, it is important to use trial and error to find an appropriate range for the horizontal variable so that you have results with both low and high power.
Example 2 - Power after a Study

This example will cover the situation in which you are calculating the power of a one-way analysis of variance $F$ test on data that have already been collected and analyzed.

An experiment included a control group and two treatment groups. Each group had seven individuals. A single response was measured for each individual and recorded in the following table.

<table>
<thead>
<tr>
<th></th>
<th>Control</th>
<th>T1</th>
<th>T2</th>
</tr>
</thead>
<tbody>
<tr>
<td>452</td>
<td>646</td>
<td>685</td>
<td></td>
</tr>

<td>649.1429</td>
</tr>
</tbody>
</table>

The significance level (Prob Level) was only 0.061—not enough for statistical significance. The researcher had hoped to show that the treatment groups had higher response levels than the control group. He could see that the group means followed this pattern since the mean for T1 was about 25% higher than the control mean and the mean for T2 was about 23% higher than the control mean. He decided to calculate the power of the experiment using these values of the means. (We do not recommend this approach because the power should be calculated for the minimum difference among the means that is of interest, not at the values of the sample means.)

The data entry for this problem is simple. The only entry that is not straight forward is finding an appropriate value for the standard deviation. Since the standard deviation is estimated by the square root of the mean square error, it is calculated as $\sqrt{11541.3} = 107.4304$. 
Setup
You can enter these values yourself or load the Example2 template from the Template tab.

Numeric Results

<table>
<thead>
<tr>
<th>Numeric Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power</td>
</tr>
<tr>
<td>0.54788</td>
</tr>
</tbody>
</table>

The power is only 0.55. That is, there was only a 55% chance of rejecting the false null hypothesis. It is important to understand this power statement is conditional, so we will state it in detail. Given that the population means are equal to the sample means (that $Sm$ is 60.01) and the population standard deviation is equal to 107.43, the probability of rejecting the false null hypothesis is 0.55. If the population means are different from the sample means (which they must be), the power is different. However, the sample means provide a reasonable place to begin.
Example 3 - Finding the Sample Size Necessary to Reject

Continuing with the last example, we will determine how large the sample size would need to have been for alpha = 0.05 and beta = 0.20.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

</tbody>
</table>

The required sample size is 12 per group or 36 subjects.
Example 4 - Using Unequal Sample Sizes

Continuing with the last example, consider the impact of allowing the group sample sizes to be unequal. Since the control group is being compared to two treatment groups, the mean of the control group is assumed to be different from those of the treatment groups. In this situation, experience has shown that adding extra subjects to the control group can increase the power. In a separate analysis, the power with 11 subjects per group was found to be 0.7851—not quite the required 0.80.

We will try moving two subjects from each treatment group into the control group. This will give an experimental design with 15 in the control group and 9 in each of the treatment groups.

Setup

Pay particular attention to how the sample size parameters were changed. The value of n is set to one so that it is essentially ignored. The Group Sample Size Pattern contains the three unequal sample sizes.

<td>0.05000</td>
<td>0.17033</td>
<td>63.34</td>
<td>107.43</td>
<td>0.5896</td>
</tr>
</tbody>
</table>

The power of 0.82967 achieved with the 33 subjects in this design is slightly higher than the power of 0.82511 that was achieved with the 36 subjects in the equal group size design. Apparently, unequal sample allocation can achieve better power!

We suggest that you try several different sample allocations. You will find that the optimum sample allocation depends on the values of the hypothesized means.

You should keep in mind that power may not be the only goal of the experiment. Other goals may include finding confidence intervals for each of the group means. And the narrowness of the width of the confidence interval is directly related to the sample size.
Example 5 - Minimum Detectable Difference

Background
It may be useful to determine the minimum detectable difference among the means that can be found at the experimental conditions. This amounts to finding \( \sigma_m \) (which we call \( Sm \) on the windows and printouts).

Problem Statement
Continuing with the previous example, find \( Sm \) for a wide range of sample sizes when alpha is 0.05 and beta is 0.10 or 0.20.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example5 template from the Template tab.

This plot shows the relationships between power, sample size, and detectable difference. Several conclusions are possible, but the most impressive is the sharp elbow in the curve that occurs near n = 10 when Sm is about 64.

How do you interpret an Sm of 64? The easiest way is to generate a set of means that have a standard deviation of 64. To do this, press the SD button in the lower right corner of the One Way ANOVA panel to load the Standard Deviation Estimator module. Set N = 3, Mean = 0, and Standard Deviation = 64. Press the Two Unique Values button. This results in three means equal to -91, 45, and 45. The differences among these means are the minimum detectable differences that can be detecting with a sample size of 9 when the power is 80%.
Example 6 - Validation using Fleiss

Background
Fleiss (1986) page 374 presents an example of determining a sample size in an experiment with 4 groups; means of 9.775, 12, 12, and 14.225; standard deviation of 3; alpha of 0.05, and beta of 0.20. He finds a sample size of 11 per group.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example6 template from the Template tab.

PASS also found n = 3.
Example 9 - Power of a Planned Comparison

An experiment is being designed to study the response to different doses of a drug. Three groups, receiving a dose of 0, 10, and 20 milligrams of the drug, are anticipated. An $F$ test will be used to test the hypothesis that the means exhibit a linear trend across the doses. The significance level is 0.05. Previous studies have shown the within group standard deviation to be 18. Treatment means of 5, 16, and 30 represent clinically important treatment differences. To better understand the relationship between power and sample size, the researcher wants to compute the power for several group sample sizes between 2 and 18. The sample sizes will be equal across all groups.

**Summary Statements**

In a one-way ANOVA study, sample sizes of 2, 2, and 2 are obtained from the 3 groups whose means are to be compared using a planned comparison (contrast). The total sample of 6 subjects achieves 17% power to detect a non-zero contrast of the means versus the alternative that the contrast is zero using an F test with a 0.05000 significance level. The value of the contrast of the means is 25.00. The common standard deviation within a group is assumed to be 18.00.

This report shows the numeric results of this power study. Most of the definitions are the same as with the one-way AOV test. Following are the definitions that are different.

**Std Dev of Means**

When displaying results for planned comparisons, this is not the standard deviation of the hypothesized means. Instead, it is a special function of the coefficients and the hypothesized means given by the equation

\[
\sigma_{mc} = \sqrt{\frac{\frac{k}{n} \sum_{i=1}^{k} c_i \mu_i}{N \sum_{i=1}^{k} \frac{c_i^2}{n_i}}}.
\]

**Effect Size**

The effect size is the ratio of SM to S. It is an index of relative difference between the means that can be compared from study to study.

This report shows the details of each row of the previous report. It is especially useful because it shows the values of the contrast coefficients and the contrast (which is the value in the lower right corner of the table).
Detail Results Report

This plot gives a visual presentation to the results in the Numeric Report. We can quickly see the impact on the power of increasing the sample size.

When you create one of these plots, it is important to use trial and error to find an appropriate range for the horizontal variable so that you have results with both low and high power.
Chapter 555

One-Way ANOVA using Simulation

Introduction

This procedure analyzes the power and significance level of the parametric F-Test and the nonparametric Kruskal-Wallis test which are used to test statistical hypotheses in a one-way experimental design. For each scenario that is set up, two simulations are run. One simulation estimates the significance level and the other estimates the power.

Technical Details

Computer simulation allows us to estimate the power and significance level that is actually achieved by a test procedure in situations that are not mathematically tractable. Computer simulation was once limited to mainframe computers. But, in recent years, as computer speeds have increased, simulation studies can be completed on desktop and laptop computers in a reasonable period of time.

The steps to a simulation study are

1. Specify how the test is carried out. This includes indicating how the test statistic is calculated and how the significance level is specified.

2. Generate random samples from the distributions specified by the alternative hypothesis. Calculate the test statistics from the simulated data and determine if the null hypothesis is accepted or rejected. Tabulate the number of rejections and use this to calculate the test’s power.

3. Generate random samples from the distributions specified by the null hypothesis. Calculate each test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. Tabulate the number of rejections and use this to calculate the test’s significance level.

4. Repeat steps 2 and 3 several thousand times, tabulating the number of times the simulated data leads to a rejection of the null hypothesis. The power is the proportion of simulated samples in step 2 that lead to rejection. The significance level is the proportion of simulated samples in step 3 that lead to rejection.
Generating Random Distributions

Two methods are available in PASS to simulate random samples. The first method generates the random variates directly, one value at a time. The second method generates a large pool (over 10,000) of random values and then draw the random numbers from this pool. This second method can cut the running time of the simulation by 70%.

As mentioned above, the second method begins by generating a large pool of random numbers from the specified distributions. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is the maximum of twice the number of simulated samples desired and 10,000.

Test Statistics

Suppose \( g \) groups each have a normal distribution and means \( \mu_1, \mu_2, \ldots, \mu_g \) and common standard deviation \( \sigma \). Let \( n_1, n_2, \ldots, n_g \) denote the number of subjects in each group and let \( N \) denote the total sample size of all groups. The tests that follow assume that the data are obtained by taking simple random samples from the \( g \) populations.

F-Test

The formula for the calculation of the F-test is

\[
F_{g-1,N-g} = \frac{MSR}{MSE}
\]

where

\[
MSR = \frac{\sum_{k=1}^{g} n_k (\bar{X}_k - \bar{X})^2}{g - 1}
\]

\[
MSE = \frac{\sum_{k=1}^{g} \sum_{j=1}^{n_k} (X_{kj} - \bar{X}_k)^2}{N - g}
\]

\[
\bar{X}_k = \frac{\sum_{j=1}^{n_k} X_{kj}}{n_k}
\]

\[
\bar{X} = \frac{\sum_{k=1}^{g} n_k \bar{X}_k}{N}
\]

\[
N = \sum_{k=1}^{g} n_k
\]
If the assumptions are met, the distribution of this test statistic follows the $F$ distribution with degrees of freedom $g-1$ and $N-g$.

**Kruskal-Wallis Test**

The Kruskal-Wallis test corrected for ties is calculated using the formula

$$W = \frac{H}{T_c}$$

where

$$H = \frac{12}{N(N+1)} \sum_{k=1}^{g} \frac{R_k^2}{n_k} - 3(N+1)$$

$$T_c = 1 - \sum \frac{t(t^2 - 1)}{N(N^2 - 1)}$$

$R_k$ is the sum of the ranks of the $k^{th}$ group, and $t$ is the count of a particular tie. The distribution of $W$ is approximately Chi-square with $g-1$ degrees of freedom.

**Procedure Options**

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

**Data Tab**

The Data tab contains most of the parameters and options that you will be concerned with.

**Find**

This option specifies the parameter to be calculated using the values of the other parameters. Under most conditions, you would select either Power or $n$.

Select Power when you want to estimate the power of a certain scenario.

Select $n$ when you want to determine the sample size needed to achieve a given power and alpha error level. This option is very computationally intensive, so it may take a long time to complete.
Simulations

This option specifies the number of iterations, \( M \), used in the simulation. The larger the number of iterations, the longer the running time, and, the more accurate the results.

The precision of the simulated power estimates are calculated from the binomial distribution. Thus, confidence intervals may be constructed for various power values. The following table gives an estimate of the precision that is achieved for various simulation sizes when the power is either 0.50 or 0.95. The table values are interpreted as follows: a 95% confidence interval of the true power is given by the power reported by the simulation plus and minus the ‘Precision’ amount given in the table.

<table>
<thead>
<tr>
<th>Simulation Size ( M )</th>
<th>Precision when Power = 0.50</th>
<th>Precision when Power = 0.95</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.100</td>
<td>0.044</td>
</tr>
<tr>
<td>500</td>
<td>0.045</td>
<td>0.019</td>
</tr>
<tr>
<td>1000</td>
<td>0.032</td>
<td>0.014</td>
</tr>
<tr>
<td>2000</td>
<td>0.022</td>
<td>0.010</td>
</tr>
<tr>
<td>5000</td>
<td>0.014</td>
<td>0.006</td>
</tr>
<tr>
<td>10000</td>
<td>0.010</td>
<td>0.004</td>
</tr>
<tr>
<td>50000</td>
<td>0.004</td>
<td>0.002</td>
</tr>
<tr>
<td>100000</td>
<td>0.003</td>
<td>0.001</td>
</tr>
</tbody>
</table>

Notice that a simulation size of 1000 gives a precision of plus or minus 0.01 when the true power is 0.95. Also note that as the simulation size is increased beyond 5000, there is only a small amount of additional accuracy achieved.

Alpha

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal means when in fact the means are equal.

Values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta

This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal means when in fact the means are different.

Values must be between zero and one. The values of 0.10 and 0.20 are often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
n (Sample Size Multiplier)

This is the base, per group, sample size. One or more values, separated by blanks or commas, may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number times each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by $m_1, m_2, m_3, \ldots, m_g$ and this value is represented by $n$, the group sample sizes $n_1, n_2, n_3, \ldots, n_g$ are calculated as follows:

$n_1 = \lceil n(m_1) \rceil$

$n_2 = \lceil n(m_2) \rceil$

$n_3 = \lceil n(m_3) \rceil$

etc.

where the operator, $\lceil X \rceil$ means the next integer after $X$, e.g. $\lceil 3.1 \rceil = 4$. This is required since sample sizes must be whole numbers.

For example, suppose there are three groups and the Group Sample Size Pattern is set to 1, 2, 3. If $n$ is 5, the resulting sample sizes will be 5, 10, and 15. If $n$ is 50, the resulting group sample sizes will be 50, 100, and 150. If $n$ is set to 2, 4, 6, 8, 10; five sets of group sample sizes will be generated and an analysis run for each. These sets are:

<table>
<thead>
<tr>
<th>2</th>
<th>4</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>8</td>
<td>12</td>
</tr>
<tr>
<td>6</td>
<td>12</td>
<td>18</td>
</tr>
<tr>
<td>8</td>
<td>16</td>
<td>24</td>
</tr>
<tr>
<td>10</td>
<td>20</td>
<td>30</td>
</tr>
</tbody>
</table>

As a second example, suppose there are three groups and the Group Sample Size Pattern is 0.2, 0.3, 0.5. When the fractional Pattern values sum to one, $n$ can be interpreted as the total sample size $N$ of all groups and the Pattern values as the proportion of the total in each group.

If $n$ is 10, the three group sample sizes would be 2, 3, and 5.

If $n$ is 20, the three group sample sizes would be 4, 6, and 10.

If $n$ is 12, the three group sample sizes would be

$(0.2)12 = 2.4$ which is rounded up to the next whole integer, 3.

$(0.3)12 = 3.6$ which is rounded up to the next whole integer, 4.

$(0.5)12 = 6$.

Note that in this case, 3+4+6 does not equal $n$ (which is 12). This can happen because of rounding.
**Group Sample Size Pattern**

A set of positive, numeric values, one for each row of distributions, is entered here. Each item specified in this list applies to the whole row of distributions. For example, suppose the entry is 1 2 1 and Grps 1 = 3, Grps 2 = 1, Grps 3 = 2. The sample size pattern used would be 1 1 2 1 1.

The sample size of group $i$ is found by multiplying the $i^{th}$ number from this list by the value of $n$ and rounding up to the next whole number. The number of values must match the number of groups, $g$. When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

**Equal**

If all sample sizes are to be equal, enter Equal here and the desired sample size in $n$. A set of $g$ 1’s will be used. This will result in $n_1 = n_2 = \ldots = n_g = n$. That is, all sample sizes are equal to $n$.

**Test Statistic**

Specify which test is to be simulated. Although the F-test is the most commonly used test, it is based on assumptions that may not be viable in some situations. For your data, you may find that the Kruskal-Wallis test is more accurate (actual alpha = target alpha) and more precise (better power).

**Specifying Simulation Distributions**

These options specify the distributions to be used in the two simulations, one set per row. The first option specifies the number of groups represented by the two distributions that follow. The second option specifies the distribution to be used in simulating the null hypothesis to determine the significance level (alpha). The third option specifies the distribution to be used in simulating the alternative hypothesis to determine the power.

**Grps k (k = 1 to 9)**

This value specifies the number of groups specified by the H0 and H1 distribution statements to the right. Usually, you will enter ‘1’ to specify a single H0 and a single H1 distribution, or you will enter ‘0’ to indicate that the distributions specified on this line are to be ignored. This option lets you easily specify many identical distributions with a single phrase.

The total number of groups $g$ is equal to the sum of the values for the three rows of distributions shown under the Data1 tab and the six rows of distributions shown under the Data2 tab.

Note that each item specified in the ‘Group Sample Size Pattern’ option applies to the whole row of entries here. For example, suppose the ‘Group Sample Size Pattern’ was ‘1 2 1’ and ‘Grps 1’ = 3, ‘Grps 2’ = 1, and ‘Grps 3’ = 2. The sample size pattern would be ‘1 1 2 1 1’.
**Group k Distribution(s) | H0**

This entry specifies the distribution of one or more groups under the null hypothesis, H0. The magnitude of the differences of the means of these distributions, which is often summarized as the standard deviation of the means, represents the magnitude of the mean differences specified under H0. Usually, the means are assumed to be equal under H0, so their standard deviation should be zero except for rounding.

These distributions are used in the simulations that estimate the actual significance level. They also specify the value of the mean under the null hypothesis, H0. Usually, these distributions will be identical. The parameters of each distribution are specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value \( M0 \) is reserved for the value of the mean under the null hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean is entered first.

- Beta = \( A(M0,A,B,Minimum) \)
- Binomial = \( B(M0,N) \)
- Cauchy = \( C(M0,Scale) \)
- Constant = \( K(Value) \)
- Exponential = \( E(M0) \)
- F = \( F(M0,DF1) \)
- Gamma = \( G(M0,A) \)
- Multinomial = \( M(P1,P2,...,Pk) \)
- Normal = \( N(M0,SD) \)
- Poisson = \( P(M0) \)
- Student's T = \( T(M0,D) \)
- Tukey's Lambda = \( L(M0,S,Skewness,Elongation) \)
- Uniform = \( U(M0,Minimum) \)
- Weibull = \( W(M0,B) \)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

**Finding the Value of the Mean of a Specified Distribution**

Except for the multinomial distribution, the distributions have been parameterized in terms of their means, since this is the parameter being tested. The mean of a distribution created as a linear combination of other distributions is found by applying the linear combination to the individual means. However, the mean of a distribution created by multiplying or dividing other distributions is not necessarily equal to applying the same function to the individual means. For example, the mean of \( 4N(4, 5) + 2N(5, 6) \) is \( 4*4 + 2*5 = 26 \), but the mean of \( 4N(4, 5) * 2N(5, 6) \) is not exactly \( 4*4*2*5 = 160 \) (although it is close).
Group k Distribution(s) | H1
Specify the distribution of this group under the alternative hypothesis, H1. This distribution is used in the simulation that determines the power. A fundamental quantity in a power analysis is the amount of variation among the group means. In fact, classical power analysis formulas, this variation is summarized as the standard deviation of the means.

The important point to realize is that you must pay particular attention to the values you give to the means of these distributions because they are fundamental to the interpretation of the simulation.

For convenience in specifying a range of values, the parameters of the distribution can be specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value \( M1 \) is reserved for the value of the mean under the alternative hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean, \( M1 \), is entered first.

- Beta = A(M1,A,B,Minimum)
- Binomial = B(M1,N)
- Cauchy = C(M1,Scale)
- Constant = K(Value)
- Exponential = E(M1)
- F = F(M1,DF1)
- Gamma = G(M1,A)
- Multinomial = M(P1,P2,…,Pk)
- Normal = N(M1,SD)
- Poisson = P(M1)
- Student’s T = T(M1,D)
- Tukey’s Lambda = L(M1,S,Skewness,Elongation)
- Uniform = U(M1,Minimum)
- Weibull = W(M1,B)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

M0 (Mean | H0)
These values are substituted for \( M0 \) in the distribution specifications given above. \( M0 \) is intended to be the value of the mean hypothesized by the null hypothesis, H0.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.

M1 (Mean | H1)
These values are substituted for \( M1 \) in the distribution specifications given above. Although it can be used wherever you want, \( M1 \) is intended to be the value of the mean hypothesized by the alternative hypothesis, H1.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.
Parameter Values (S, A, B, C)
Enter the numeric value(s) of the parameters listed above. These values are substituted for the corresponding letter in all four distribution specifications.

You can enter a list of values for each letter using the syntax 0 1 2 3 or 0 to 3 by 1.
You can also change the letter that is used as the name of this parameter using the pull-down menu to the side.

Options Tab
The Options tab contains limits on the number of iterations and various options about individual tests.

Maximum Iterations
Specify the maximum number of iterations before the search for the sample size is aborted. When the maximum number of iterations is reached without convergence, the sample size is left blank. We recommend a value of at least 500.

Random Number Pool Size
This is the size of the pool of values from which the random samples will be drawn. Pools should be at least the maximum of 10,000 and twice the number of simulations. You can enter Automatic and an appropriate value will be calculated.
If you do not want to draw numbers from a pool, enter 0 here.

Reports Tab
The Reports tab contains settings about the format of the output.

Show Numeric Reports & Plots
These options let you specify whether you want to generate the standard reports and plots.

Show Inc’s & 95% C.I.
Checking this option causes an additional line to be printed showing a 95% confidence interval for both the power and actual alpha and half the width of the confidence interval (the increment).

Show Comparative Reports & Plots
These options let you specify whether you want to generate reports and plots that compare the test statistics that are available.
Example1 - Power at Various Sample Sizes

For this first example we repeat Example 1 of the regular One-Way ANOVA procedure. This will allow you to compare the values obtained by simulation with the actual values obtained from the theoretical results.

An experiment is being designed to compare the means of four groups using an $F$ test with a significance level of 0.05. Previous studies have shown that the standard deviation within a group is 18. Treatment means of 40, 10, 10, and 10 represent clinically important treatment differences. To better understand the relationship between power and sample size, the researcher wants to compute the power for group sample sizes of 4, 8, and 12. The group sample sizes are equal.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

Notes:

- **Pool Size**: 10000.
- **Simulations**: 2000.
- **Run Time**: 12.84 seconds.

**H0 Distributions**: Normal(M0 S); Normal(M0 S); Normal(M0 S); and Normal(M0 S)

**H1 Distributions**: Normal(M1 S); Normal(M0 S); Normal(M0 S); and Normal(M0 S)

Report Definitions

- **H0** represents the null hypothesis.
- **H1** represents the alternative hypothesis.
- 'n' is the average of the group sample sizes.
- Total N is the total sample size of all groups combined.
- Target Alpha is the desired probability of rejecting a true null hypothesis.
- Actual Alpha is the alpha achieved by this simulation.
- Beta is the probability of accepting a false null hypothesis.
- S.D.|H1 is the standard deviation of the group means under the alternative hypothesis.
- S.D.|H1 is the within group standard deviation under the alternative hypothesis.

Second Row: (Power Prec.) [95% LCL and UCL Power] (Alpha Prec.) [95% LCL and UCL Alpha]

Summary Statements

A one-way design with 4 groups has sample sizes of 4, 4, 4, and 4. The null hypothesis is that the standard deviation of the group means is 0.1 and the alternative standard deviation of the group means is 13.0. The total sample of 16 subjects achieves a power of 0.536 using the F-Test with a target significance level of 0.050 and an actual significance level of 0.047. The average within group standard deviation assuming the alternative distribution is 18.0. These results are based on 2000 Monte Carlo samples from the null distributions: Normal(M0 S); Normal(M0 S); Normal(M0 S); and Normal(M0 S) and the alternative distributions: Normal(M1 S); Normal(M0 S); Normal(M0 S); and Normal(M0 S). Other parameters used in the simulation were: M0 = 10.0, M1 = 40.0, and S = 18.0.

This report shows the estimated power for each scenario. The first row shows the parameter settings and the estimated power and significance level (Actual Alpha).

The second row shows two 95% confidence intervals in brackets: the first for the power and the second for the significance level. Half the width of each confidence interval is given in parentheses as a fundamental measure of the accuracy of the simulation. As the number of simulations is increased, the width of the confidence intervals will decrease.

**Power**

This is the probability of rejecting a false null hypothesis. This value is estimated by the simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values are provided to help you understand the precision of the estimated power.
**Average Group Size n**  
This is the average of the group sample sizes.

**Total Sample Size N**  
This is the total sample size of the study.

**Target Alpha**  
The target value of alpha: the probability of rejecting a true null hypothesis. This is often called the significance level.

**Actual Alpha**  
This is the value of alpha estimated by the simulation using the H0 distributions. It should be compared with the Target Alpha to determine if the test statistic is accurate in this scenario.  
Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values are provided to help you understand the precision of the Actual Alpha.

**Beta**  
Beta is the probability of accepting a false null hypothesis. This is the value of beta estimated by the simulation using the H1 distributions.

**S.D. of Means Sm|H1**  
This is the standard deviation of the hypothesized means of the alternative distributions. Under the null hypothesis, this value is zero. So this value represents the magnitude of the difference among the means that is being tested. It is roughly equal to the average difference between the group means and the overall mean.  
Note that the effect size is the ratio of Sm|H1 and SD|H1.

**S.D. of Data SD|H1**  
This is the within-group standard deviation calculated from samples from the alternative distributions.

**M0**  
This is the value entered for M0, the group means under H0.

**M1**  
This is the value entered for M1, the group means under H1.

**S**  
This is the value entered for S, the standard deviation.

This report shows the details of each row of the previous report.

**Group**
This is the number of the group shown on this line. The first line, labeled *All*, gives the average or the total as appropriate.

**Ni**
This is the sample size of each group. This column is especially useful when the sample sizes are unequal.

**Percent Ni of N**
This is the percentage of the total sample that is allocated to each group.

**H0 and H1 Means**
These are the means that were used in the simulations for H0 and H1, respectively.

**H0 and H1 S.D.’s**
These are the standard deviations that were obtained by the simulations for H0 and H1, respectively. Note that they often are not exactly equal to what was specified because of simulation error.

**H0 and H1 Sm’s**
These are the standard deviations of the means that were obtained by the simulations for H0 and H1, respectively. Under H0, the value of Sm should be near zero. It lets you determine if your simulation of H0 was correctly specified.
Plot Section

This plot gives a visual presentation to the results in the Numeric Report. We can quickly see the impact on the power of increasing the sample size.
Example2 - Comparative results

Continuing with Example1, the researchers want to study the characteristics of alternative test statistics. They want to compare the results of the F-test and the Kruskal-Wallis test.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example2 template from the Template tab.

**Power vs n by Test with M0=10.0 M1=40.0 S=18.0 Alpha=0.05**

We notice that the power of the F-test is much greater than the Kruskal-Wallis test for \( n = 4 \). However, when \( n = 12 \), the powers of the two tests are almost equal. Note that the alpha value of the Kruskal-Wallis test is almost half that of the F-test for \( n = 4 \). This is probably why the power is also low.
Example3 - Validation using Fleiss

Fleiss (1986) page 374 presents an example of determining an appropriate sample size when using an F-test in an experiment with 4 groups; means of 9.775, 12, 12, and 14.225; standard deviation of 3; alpha of 0.05, and beta of 0.20. He finds a sample size of 11 per group.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

Option | Value
--- | ---
Data Tab | Power
Find | Simulations: 2000
Alpha | 0.05
Beta | 0.20
n (Multiplier) | Ignored since this is the Find setting
Group Sample Size Pattern | Equal

Note that **PASS** has also found the group sample size to be 11.
Example 4 - Selecting a test statistic when the data contain outliers

The F-test is known to be robust to the violation of some assumptions, but it is susceptible to inaccuracy when the data contain outliers. This example will investigate the impact of outliers on the power and precision of the F-test and the Kruskal-Wallis test.

A mixture of two normal distributions will be used to randomly generate outliers. The mixture will draw 95% of the data from a normal distribution with mean zero and variance one. The other 5% of the data will come from a normal distribution with mean zero and variance that ranges from one to ten. In the alternative distributions, two will have a mean of zero and one will have a mean of one.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example 4 template from the Template tab.

### Power vs A by Test with M0=0.0 M1=1.0 S=1.0 Alpha=0.05 n=10

We note that when the variances are equal (A = 1), the F-Test is slightly better than the Kruskal-Wallis test. However, as the number of outliers is increased, the F-test does increasingly worse both in terms of power and significance, but the Kruskal-Wallis test is considerably less affected.
Example5 - Selecting a test statistic when the data are skewed

The F-test is known to be robust to the violation of some assumptions, but it is susceptible to inaccuracy when the underlying distributions are skewed. This example will investigate the impact of skewness on the power and precision of the F-test and the Kruskal-Wallis test.

Tukey’s lambda distribution will be used because it allows the amount of skewness to be gradually increased.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example5 template from the Template tab.

We note that as the skewness increases, the power of the Kruskal-Wallis test increases substantially as compared to the F-test.
Chapter 560

Fixed Effects Analysis of Variance

Introduction

A common task in research is to compare the average response across levels of one or more factor variables. Examples of factor variables are income level of two regions, nitrogen content of three lakes, or drug dosage. The fixed-effects analysis of variance compares the means of two or more factors. $F$ tests are used to determine statistical significance of the factors and their interactions. The tests are nondirectional in that the null hypothesis specifies that all means are equal and the alternative hypothesis simply states that at least one mean is different. This PASS module performs power analysis and sample size estimation for an analysis of variance design with up to three factors.

In the following example, the responses of a weight loss experiment are arranged in a two-factor, fixed-effect, design. The first factor is diet (D1 and D2) and the second factor is dose level of a dietary drug (low, medium, and high). The twelve individuals available for this study were assigned at random to one of the six treatment groups (cells) so that there were two per group. The response variable was an individual’s weight loss after four months.

<table>
<thead>
<tr>
<th>Table of Individual Weight Losses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diet</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>D1</td>
</tr>
<tr>
<td>D2</td>
</tr>
</tbody>
</table>

Important features to note are that each table entry represents a different individual and that the response variable (weight loss) is continuous, while the factors (Diet and Dose) are discrete.

Means can be calculated for each cell of the table. These means are shown in the table below. Note that we have added an additional row and column for the row, column, and overall means. The six means in the interior of this table are called the cell means.
### The Linear Model

A mathematical model may be formulated that underlies this experimental design. This model expresses each cell mean, \( \mu_{ij} \), as the sum of parameters called effects. A common linear model for a two-factor experiment is

\[
\mu_{ij} = m + a_i + b_j + (ab)_{ij}
\]

where \( i = 1, 2, ..., I \) and \( j = 1, 2, ..., J \). This model expresses the value of a cell mean as the sum of four components:

- \( m \) the grand mean.
- \( a_i \) the effect of the \( i^{th} \) level of factor \( A \). Note that \( \sum a_i = 0 \).
- \( b_j \) the effect of the \( j^{th} \) level of factor \( B \). Note that \( \sum b_j = 0 \).
- \( ab_{ij} \) the combined effect of the \( i^{th} \) level of factor \( A \) and the \( j^{th} \) level of factor \( B \). Note that \( \sum (ab)_{ij} = 0 \).

Another way of stating this model for the two factor case is

\[
\text{Cell Mean} = \text{Overall Effect} + \text{Row Effect} + \text{Column Effect} + \text{Interaction Effect}.
\]

Since this model is the sum of various constants, it is called a *linear model*.  

---

### Table of Means

<table>
<thead>

</thead>
<tbody>
<tr>
<td><strong>Diet</strong></td>
<td>Low</td>
</tr>
<tr>
<td>D1</td>
<td>15.00</td>
</tr>
<tr>
<td>D2</td>
<td>19.50</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>17.25</td>
</tr>
</tbody>
</table>
Calculating the Effects
We will now calculate the effects for our example. We will let Drug Dose correspond to factor A and Diet correspond to factor B.

Step 1 - Remove the grand mean
Remove the grand mean from the table of means by subtracting 22.50 from each entry. The values in the margins are the effects of the corresponding factors.

Table of Mean Weight Losses After Subtracting the Grand Mean

<table>
<thead>
<tr>
<th>Dietary Drug Dose Level</th>
<th>Diet</th>
<th>Low</th>
<th>Medium</th>
<th>High</th>
<th>Overall</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>D1</td>
<td>-7.50</td>
<td>-6.00</td>
<td>3.00</td>
<td>-3.50</td>
</tr>
<tr>
<td></td>
<td>D2</td>
<td>-3.00</td>
<td>-2.50</td>
<td>16.00</td>
<td>3.50</td>
</tr>
<tr>
<td></td>
<td>Overall</td>
<td>-5.25</td>
<td>-4.25</td>
<td>9.50</td>
<td>22.50</td>
</tr>
</tbody>
</table>

Step 2 - Remove the effects of factor B (Diet)
Subtract the Diet effects (-3.50 and 3.50) from the entries in those rows.

Table of Mean Weight Losses After Subtracting the Diet Effects

<table>
<thead>
<tr>
<th>Dietary Drug Dose Level</th>
<th>Diet</th>
<th>Low</th>
<th>Medium</th>
<th>High</th>
<th>Overall</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>D1</td>
<td>-4.00</td>
<td>-2.50</td>
<td>6.50</td>
<td>-3.50</td>
</tr>
<tr>
<td></td>
<td>D2</td>
<td>-6.50</td>
<td>-6.00</td>
<td>12.50</td>
<td>3.50</td>
</tr>
<tr>
<td></td>
<td>Overall</td>
<td>-5.25</td>
<td>-4.25</td>
<td>9.50</td>
<td>22.50</td>
</tr>
</tbody>
</table>
Step 3 - Remove the effects of factor A (Drug Dose)

Subtract the Drug Dose effects (-5.25, -4.25, and 9.50) from the rest of the entries in those columns. This will result in a table of effects.

<table>
<thead>
<tr>
<th>Dietary Drug Dose Level</th>
<th>Low</th>
<th>Medium</th>
<th>High</th>
<th>Overall</th>
</tr>
</thead>
<tbody>
<tr>
<td>D1</td>
<td>1.25</td>
<td>1.75</td>
<td>-3.00</td>
<td>-3.50</td>
</tr>
<tr>
<td>D2</td>
<td>-1.25</td>
<td>-1.75</td>
<td>3.00</td>
<td>3.50</td>
</tr>
<tr>
<td>Overall</td>
<td>-5.25</td>
<td>-4.25</td>
<td>9.50</td>
<td>22.50</td>
</tr>
</tbody>
</table>

We have calculated a table of effects for the two-way linear model. Each cell mean can calculated by summing the appropriate entries from this table.

The estimated linear effects are:

m = 22.50
a1 = -5.25
a2 = -4.25
a3 = 9.50
b1 = -3.50
b2 = 3.50
ab11 = 1.25
ab21 = 1.75
ab31 = -3.00
ab12 = -1.25
ab22 = -1.75
ab32 = 3.00

The six cell means are calculated from these effects as follows:

15.00 = 22.50 - 5.25 - 3.50 + 1.25
19.50 = 22.50 - 5.25 + 3.50 - 1.25
16.50 = 22.50 - 4.25 - 3.50 + 1.75
20.00 = 22.50 - 4.25 + 3.50 - 1.75
25.50 = 22.50 + 9.50 - 3.50 - 3.00
38.50 = 22.50 + 9.50 + 3.50 + 3.00

Analysis of Variance Hypotheses

The hypotheses that are tested in an analysis of variance table concern the effects, so in order to conduct a power analysis you must have a firm grasp of their meaning. For example, we would usually test the following hypotheses:

1. Are there differences in weight loss among the three drug doses? That is, are the drug dose effects all zero? This hypothesis is tested by the $F$ test for factor $A$, which tests whether the standard deviation of the $a_i$ is zero.

2. Is there a difference in weight loss between the two diets? That is, are the diet effects all zero? This hypothesis is tested by the $F$ test for factor $B$, which tests whether the standard deviation of the $b_j$ is zero.
3. Are there any diet-dose combinations that exhibit a weight loss that cannot be explained by diet and/or drug dose singly? This hypothesis is tested by the $F$ test for the $AB$ interaction, which tests whether the standard deviation of the $(ab)_{ij}$ is zero.

Each of these hypotheses can be tested at a different alpha level and different precision. Hence each can have a different power. One of the tasks in planning such an experiment is to determine a sample size that yields necessary power values for each of these hypothesis tests. This is accomplished using this program module.

**Definition of Terms**

Factorial designs evaluate the effect of two or more categorical variables (called *factors*) on a response variable by testing hypotheses about various averages. These designs are popular because they allow experimentation across a wide variety of conditions and because they evaluate the *interaction* of two or more factors. Interaction is the effect that may be attributed to a combination of two or more factors, but not to one factor singly.

A *factor* is a variable that relates to the response. Either the factor is discrete by nature (as in location or gender) or has been made discrete by collapsing a continuous variable (as in income level or age group). The term *factorial* implies that all possible combinations of the factors being studied are included in the design.

A *fixed* factor is one in which all possible *levels* (categories) are considered. Examples of fixed factors are gender, dose level, and country of origin. They are different from *random* factors which represent a random selection of individuals from the population described by the factor. Examples of random factors are people living within a region, a sample of schools in a state, or a selection of labs. Again, a fixed factor includes the range of interest while a random factor includes only a sample of all possible levels.

A factorial design is analyzed using the analysis of variance. When only fixed factors are used in the design, the analysis is said to be a *fixed-effects analysis of variance*. Other types of designs will be discussed in later chapters.

Suppose a group of individuals have agreed to be in a study involving six treatments. In a *completely randomized factorial design*, each individual is assigned at random to one of the six groups and then the treatments are applied. In some situations, the randomization occurs by randomly selecting individuals from the populations defined by the treatment groups. The designs analyzed by this module are completely randomized factorial designs.

## Power Calculations

The calculation of the power of a particular test proceeds as follows

1. Determine the critical value, $F_{df_1, df_2, \alpha}$ where $df1$ is the numerator degrees of freedom, $df2$ is the denominator degrees of freedom, and $\alpha$ is the probability of a type-I error (significance level). Note that the $F$ test is a two-tailed test as no logical direction is assigned in the alternative hypothesis.

2. Calculate the standard deviation of the hypothesized effects, using the formula:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - \bar{e})^2}{k}}$$

where the $e_i$ are effect values and $k$ is the number of effects. Note that the average effect will be zero by construction, so this formula reduces to

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} e_i^2}{k}}$$

3. Compute the noncentrality parameter $\lambda$ using the relationship:

$$\lambda = N \frac{\sigma_m^2}{\sigma^2}$$

where $N$ is the total number of subjects.

4. Compute the power as the probability of being greater than $F_{df_1, df_2, \alpha}$ on a noncentral-$F$ distribution with noncentrality parameter $\lambda$.

### Example

In the example discussed earlier, the standard deviation of the dose effects is

$$\sigma_m(A) = \sqrt{\frac{(-5.25)^2 + (-4.25)^2 + 9.50^2}{3}}$$

$$= 6.729908$$

the standard deviation of the diet effects is

$$\sigma_m(B) = \sqrt{\frac{(-3.5)^2 + 3.5^2}{2}}$$

$$= 3.5$$

and the standard deviation of the interaction effects is

$$\sigma_m(AB) = \sqrt{\frac{1.25^2 + (-1.25)^2 + 1.75^2 + (-1.75)^2 + (-3.00)^2 + 3.00^2}{6}}$$

$$= 2.131119$$
Change in Calculation from PASS 6.0

In PASS 6.0, we used the approach of Cohen (1988) to calculate $\lambda$. However, we have found that Cohen’s method is less accurate in some situations. Here’s why. Cohen produced a set of tables for the one-way AOV which he extended to the two-way and three-way cases by adjusting the per group sample size (his $n'$) so that the denominator degrees of freedom were accurate. However, his adjustment also causes a change in $\lambda$ which can cause a substantial difference in the calculated power. By using the formula

$$
\lambda = N \frac{\sigma_m^2}{\sigma^2}
$$

we now calculate the correct power. This is why our calculations differ from that of Cohen (1988) for fixed factorial models.

Standard Deviation of Effects (of Means)

In the two-sample t-test case, the alternative hypothesis was represented as the difference between two group means. Unfortunately, for three or more groups, there is no simple extension of the two group difference. Instead, you must hypothesize a set of effects and calculate the value of $\sigma_m$.

Some might wish to specify the alternative hypothesis as the effect size, $f$, which is defined as

$$
f = \frac{\sigma_m}{\sigma}
$$

where $\sigma$ is the standard deviation of values within a cell (see Sigma below). If you want to use $f$, set $\sigma = 1$ and then $f$ is always equal to $\sigma_m$ so that the values you enter for $\sigma_m$ will be the values of $f$. Cohen (1988) has designated values of $f$ less than 0.1 as small, values around 0.25 to be medium, and values over 0.4 to be large. You should come up with your own cutoff values for low, medium, and high.

When you are analyzing the power of an existing analysis of variance table, you can compute the values of $\sigma_m$ for each term from its mean square or $F$ ratio using the following formulas:

$$
\sigma_m = \sqrt{\frac{df_{\text{numerator}} MS_{\text{numerator}}}{N}}
$$

or

$$
\sigma_m = \sqrt{\frac{df_{\text{numerator}} (F)(MSE)}{N}}
$$

where $N$ is the total number of observations, $MSE$ is the mean square error, $df$ is the numerator degrees of freedom, $MS$ is the mean square of the term, and $F$ is the $F$ ratio of the term. If you do this, you are setting the sample effects equal to the population effects for the purpose of computing the power.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data and Reports tabs. To find out more about using the other tabs, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Factors (A, B, C) & Interactions (AB, ..., ABC)

These check boxes specify which terms are included in the analysis of variance model. Check a term to signify that it must be included in the analysis.

The three factors are assigned the labels A, B, and C. The interaction between factors A and B is labeled AB. The three-way interaction is labeled ABC.

You cannot include an interaction term without including all shorter terms that make up that interaction. For example, if you include the interaction AC, you must also include the terms A and C. Similarly, if you include the term ABC, you must also include the terms A, B, C, AB, AC, and BC.

Categories (A, B, and C)

These options specify the number of categories (levels) contained in each factor. Since the total sample size is equal to the product of the number of levels in each factor and the number of observations per cell (N Per Cell), increasing the number of levels of a factor increases the total sample size of the experiment.

Hypothesized Means (A, B, C)

Enter a set of hypothesized means (or effects), one for each factor level. The standard deviation of these means is used in the power calculations. The standard deviation is calculated using the formula:

\[
\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (\mu_i - \bar{\mu})^2}{k}}
\]

where \(k\) is the number of effects. Note that the standard deviation will be the same whether you enter means or effects since the average of the effects is zero by definition.

Enter a set of means that give the pattern of differences you expect or the pattern that you wish to detect. For example, in a particular study involving a factor with three categories, your research might be meaningful if either of two treatment means is 50% larger than the control mean. If the control mean is 50, then you would enter 50, 75, 75 as the three means.

It is usually more intuitive to enter a set of mean values. However, it is possible to enter the standard deviation of the means directly by placing an S in front of the number.
**Entering a list of means**

If numbers are entered without a leading $S$, they are assumed to be the hypothesized group means under the alternative hypothesis. Their standard deviation will be calculated and used in the calculations. Blanks or commas may separate the numbers. Note that it is not the values of the means themselves that is important, but only their differences. Thus, the mean values 0, 1, 2 produce the same results as the values 100, 101, 102.

If not enough means are entered to match the number of groups, the last mean is repeated. For example, suppose that four means are needed and you enter 1, 2 (only two means). **PASS** will treat this as 1, 2, 2, 2. If too many values are entered, **PASS** will truncate the list to the number of means needed.

Examples:

5 20 60
2, 5, 7
-4, 0, 6, 9

**S Option**

If an $S$ is entered before a number, the number is assumed to be the value of $\sigma_m$, the standard deviation of the means.

Examples:

S 4.7
S 5.7

**Hypothesized Effects**

Specify the standard deviation of the interaction effects using one of the following methods:

1. Enter a set of effects and let the program calculate their standard deviation (see below).
2. Enter the standard deviation directly.
3. Instruct the program to make the standard deviation proportional to one of the main effect terms.

The standard deviation of the effects is calculated using the formula:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - \bar{e})^2}{k}}$$

$$= \sqrt{\frac{\sum_{i=1}^{k} e_i^2}{k}}$$

where $k$ is the number of effects and $e_1, e_2, \ldots, e_k$ are the effect values. The value of $\bar{e}$ may be ignored because it is zero by definition.
**Syntax**

**Entering a list of effects**

If numbers are entered without a leading letter, they are assumed to be the hypothesized effects under the alternative hypothesis (they are all assumed to be zero under the null hypothesis). Their standard deviation will be calculated and used in the calculations. Blanks or commas may separate the numbers.

If not enough effects are entered to match the number of levels in the term, the last effect is repeated. For example, suppose that four effects are needed and you enter 1,2 (only two effects). **PASS** will treat this as 1,2,2,2. If too many values are entered, **PASS** will truncate the list to the number of effects needed.

For interactions, the number of effects is equal to the product of the number of levels of each factor in the interaction. For example, suppose a two-factor design has one factor with three levels and another factor with five levels. The number of effects in the two-factor interaction is (3)(5) = 15.

**Examples (note that they sum to zero):**

-1 1 -3 3  
2 2 0 -1 -1 -2  
-4,0,1,3

**S Option**

If an S is followed by a number, the number is assumed to be the value of $\sigma_m$, the standard deviation of the effects.

When a set of effects are equal to either $e$ or $-e$, the formula for the standard deviation may be simplified as follows:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - 0)^2}{k}}$$

$$= \sqrt{\frac{\sum_{i=1}^{k} e^2}{k}}$$

$$= e$$

Hence, another interpretation of $\sigma_m$ is the absolute value of a set of effects that are equal, except for the sign.

**Example:**

S 4.7
Enter a Term Followed by a Percentage

You can enter the name of a previous term followed by a percentage. This instructs the program to set this standard deviation to $x\%$ of the term you specify, where $x$ is a positive integer. This allows you to set the magnitude of the interaction standard deviation as a percentage of another term without specifying the interaction in detail.

Note that the term you are taking a percentage of must appear above the term you are specifying. That is, you cannot specify $AB \ 50$ for factor $C$ (since only $A$ and $B$ occur above $C$ on the screen).

For example, if the standard deviation of factor $A$ is 16, the command

A 75

will set the standard deviation of the current term to $(16)(75)/(100) = 12.0$.

Other examples of this syntax are:

A 50
B 25
AB 125
AC 150

Discussion

The general formula for the calculation of the standard deviation is

$$\sigma_m = \sqrt{\frac{\sum_{j=1}^{k} (e_j)^2}{k}}$$

where $k$ is the number of effects. In the case of a two-way interaction, the standard deviation is calculated using the formula:

$$\sigma_n(AB) = \sqrt{\frac{\sum_{i=1}^{I} \sum_{j=1}^{J} (\mu_{ij} - \mu_{i\cdot} - \mu_{\cdot j} + \overline{\mu})^2}{IJ}}$$

where $i$ is the factor $A$ index (from 1 to $I$), $j$ is the factor $B$ index (from 1 to $J$), $\mu_{ij}$ is the mean in the $ij^{th}$ cell, $\mu_{i\cdot}$ is the $i^{th}$ mean of factor $A$ across all levels of other factors, $\mu_{\cdot j}$ is the $j^{th}$ mean when factor $B$ across all levels of other factors, and $\overline{\mu}$ is the overall mean of the means.
To see how this works, consider the following table of means from an experiment with $I = 2$ and $J = 3$:

<table>
<thead>
<tr>
<th>$i$</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.0</td>
<td>4.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>6.0</td>
</tr>
<tr>
<td>3</td>
<td>6.0</td>
<td>11.0</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Total</td>
<td>4.0</td>
<td>7.0</td>
</tr>
</tbody>
</table>

Now, if we subtract the factor $A$ means, subtract the factor $B$ means, and add the overall mean, we get the interaction effects:

- $0.5 - 0.5$
- $0.5 - 0.5$
- $-1.0 + 1.0$

Next, we sum the squares of these six values:

$$
\left(0.5\right)^2 + \left(-0.5\right)^2 + \left(0.5\right)^2 + \left(-0.5\right)^2 + \left(-1.0\right)^2 + \left(1.0\right)^2 = 3
$$

Next we divide this value by $(2)(3) = 6$:

$$3 / 6 = 0.5$$

Finally, we take the square root of this value:

$$\sqrt{0.5} = 0.7071$$

Hence, for this configuration of means,

$$\sigma_m(AB) = 0.7071.$$ 

Notice that the average of the absolute values of the interaction effects is:

$$[0.5 + 0.5 + 0.5 + 0.5 + 1.0 + 1.0]/6 = 0.6667$$

We see that $SD(interaction)$ is close to the average absolute interaction effect. That is, $0.7071$ is close to $0.6667$. This will usually be the case. Hence, one way to interpret the interaction standard deviation is as a number a little larger than the average absolute interaction effect.
**Alpha**

These options specify the significance levels (the probability of a type-I error) of each term. A type-I error occurs when you reject the null hypothesis of that all effects are zero when in fact they are.

Since they are probabilities, alpha values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This value may be interpreted as meaning that about one \( F \) test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

You can select different alpha values for different terms. For example, although you have three factors in an experiment, you might be mainly interested in only one of them. Hence, you could increase the alpha level of the tests from, for example, 0.05 to 0.10 and thereby increase their power. Also, you may want to increase the alpha level of the interaction terms, since these will often have poor power otherwise.

**N per Cell**

This is the sample size within a cell. Fractional values are allowed. When you have an unequal number of observations per cell, enter the average cell sample size.

If you enter more than one value, a separate analysis will be generated for each value.

**S (Std Dev of Subjects)**

This option specifies the value of the standard deviation (\( \sigma \)) within a cell (the analysis of variance assumes that \( \sigma \) is constant across all cells). Since they are positive square roots, the numbers must be strictly greater than zero. You can press the SD button to obtain further help on estimating the standard deviation.

This value may be estimated from a previous analysis of variance table by the square root of the mean square error.

If you want to use the effect size, \( f \), as the measure of the variability of the effects, you can use 1.0 for \( \sigma \).
Example 1 - Power after a study

This example will explain how to calculate the power of $F$ tests from data that have already been collected and analyzed.

Analyze the power of the experiment that was given at the beginning of this chapter. These data were analyzed using the analysis of variance procedure in NCSS and the following results were obtained.

</tbody>
</table>

**Setup**

To analyze these data, we can enter the means for factors $A$ and $B$ as well as the $AB$ interaction effects.

Alternatively, we could have calculated the standard deviation of the interaction. This can be done in either of two ways.

Using mean square for $AB$ (27.25), the degrees of freedom for $AB$ (2), and the total sample size (12), the standard deviation of the $AB$-interaction effects is calculated as follows

$$
\sigma_m(AB) = \sqrt{ \frac{2(27.25)}{12} } = 2.1311
$$

Using the formula based on the effects, the standard deviation of the $AB$-interaction effects is calculated as follows

$$
\sigma_m(AB) = \sqrt{ \frac{3^2 + 3^2 + 1.25^2 + 1.25^2 + 1.75^2 + 1.75^2}{6} } = 2.1311
$$
The value of $\sigma$ is estimated from the square root of the mean square error:

$$\sigma = \sqrt{5.333333} = 2.3094$$

You can enter these values yourself or load the Example1 template from the Template tab.

### Option Values

**Data Tab**

Standard Deviation Within Subjects = 2.3094

**Summary Statements**

A factorial design with two factors at 3 and 2 levels has 6.0 cells (treatment combinations). A total of 12.0 subjects are required to provide 2.0 subjects per cell. The within-cell standard deviation is 2.3094. This design achieves 100% power when an F test is used to test factor A at a 5% significance level and the actual standard deviation among the appropriate means is 6.7299 (an effect size of 2.914), achieves 99% power when an F test is used to test factor B at a 5% significance level and the actual standard deviation among the appropriate means is 3.5000 (an effect size of 1.516), and achieves 59% power when an F test is used to test the AB interaction at a 5% significance level and the actual standard deviation among the appropriate means is 2.1312 (an effect size of 0.923).

This report shows the power for each of the three factors. Note that these power values match those given by the NCSS program in the analysis of variance report.

It is important to emphasize that these power values are for the case when the effects associated with the alternative hypotheses are equal to those given by the data. It will often be informative to calculate the power for other values as well.
**Term**
This is the term (main effect or interaction) from the analysis of variance model being displayed on this line.

**Power**
This is the power of the $F$ test for this term. Note that since adding and removing terms changes the denominator degrees of freedom ($df_2$), the power depends on which other terms are included in the model.

**n**
This is the sample size per cell (treatment combination). Fractional values indicate an unequal allocation among the cells.

**Total N**
This is the total sample size for the complete design.

**df1**
This is the numerator degrees of freedom of the $F$ test.

**df2**
This is the denominator degrees of freedom of the $F$ test. This value depends on which terms are included in the AOV model.

**Std Dev of Means (Sm)**
This is the standard deviation of the means (or effects). It represents the size of the differences among the effects that is to be detected by the analysis. If you have entered hypothesized means, only their standard deviation is displayed here.

**Effect Size**
This is the standard deviation of the means divided by the standard deviation of subjects. It provides an index of the magnitude of the difference among the means that can be detected by this design.

**Alpha**
This is the significance level of the $F$ test. This is the probability of a type-I error given the null hypothesis of equal means and zero effects.

**Beta**
This is the probability of the type-II error for this test given the sample size, significance level, and effect size.
Example 2 - Finding the sample size

Background
In this example, we will investigate the impact of increasing the sample size on the power of each of the seven tests in the analysis of variance table of a three factor experiment. The first factor ($A$) has two levels, the second factor ($B$) has three levels, and the third factor ($C$) has four levels. This creates a design with $2 \times 3 \times 4 = 24$ treatment combinations.

All values of $\sigma_m$ will be set equal to 0.2, $\sigma$ is set equal to 1.0, and alpha is set to 0.05.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example2 template from the Template tab.

</tbody>
</table>

A few interesting features of this report stand out. First note the range of power values across the range of sample size values tested. Reasonable power is not reached until \( n \) is 16. Also note that as the number of numerator degrees of freedom (\( df_1 \)) increases, the power decreases, other things being equal. We must use this knowledge when planning for appropriate power in tests of important interaction terms.

There are a lot of additional runs that you might try. For example, you might look at the impact of setting the alpha level of interaction terms 0.08. You might look at varying \( \sigma_m \) across the different terms. You might try varying the number of levels of a factor. All of these will impact the power of the \( F \) tests and will thus be important to consider during the planning stage of an experiment.
Example 3 - Latin Square

Background
This example shows how to study the power of a complicated experimental design like a Latin square. Suppose you want to run a Five-Level Latin square design. Recall that a Five-Level Latin square design consists of three factors each at five levels. One factor is associated with the columns of the square, a second factor is associated with the rows of the square, and a third factor is associated with the letters of the square. In all there are only $5 \times 5 = 25$ observations used instead of the $5 \times 5 \times 5 = 125$ that would normally be required. The Latin square design has reduced the number of observations by 80%.

The 80% decrease in observations comes at a price—the interaction terms must be ignored. If you can legitimately assume that the interactions are zero, the Latin square (or some other design which reduces the number of observations) is an efficient design to use. We will now show you how to analyze the power of the $F$ tests from such a design.

The key is to enter 0.2 (which is 25/125) for $n$ and set all the interaction indicators off.

Problem Statement
Since all three factors have five levels, the power of the three $F$ tests will be the same if $\sigma_m$ is the same. Hence, we can try three different sets of hypothesized means. The first set will be five means 0.1 units apart. The second set will be five means 0.5 units apart. The third set will be five means 1.0 unit apart. The standard deviation will be set to 1.0. All alpha levels will be set at 0.05.

The sample size per cell is set at 0.2 and 0.4. This will result in total sample sizes of 25 (one replication) and 50 (two replications).

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

</tr>
</tbody>
</table>

Standard Deviation of Subjects = 1.000

In the first design in which \( N = 25 \), only the power of the test for \( C \) is greater than 0.8. Of course, this power value also depends on the value of the standard deviation of subjects within a cell.

It is interesting to note that doubling the sample size did not double the power!
Example 4 - Validation using Winer

Winer (1991) pages 428-429 presents the power calculations for a two-way design in which factor A has two levels and factor B has three levels. Winer provides estimates of the sum of squared A effects (1.0189), sum of squared B effects (5.06), and sum of squared interaction effects (42.11). The mean square error is 8.83 and the per cell sample size is 3. All alpha levels are set to 0.05.

Winer’s results are approximate because he has to interpolate in the tables that he is using. He finds the power of the F test for factor A to be between 0.10 and 0.26. He estimates it as 0.17. The exact power of the F test for factor B is not given. Instead, the range is found to be between 0.26 and 0.36. The power of the F test for the AB interaction is “approximately” 0.86.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example4 template from the Template tab.

<td>0.05000</td>
<td>0.14662</td>
</tr>
</tbody>
</table>

Standard Deviation of Subjects = 2.970

The power of the test for factor A is 0.16 which is between 0.10 and 0.26. It is close to the interpolated 0.17 that Winer obtained from his tables.

The power of the test for factor B is 0.29 which is between 0.26 and 0.36.

The power of the test for the AB interaction is 0.85 which is close to the interpolated 0.86 that Winer obtained from his tables.
Example 5 - Validation using Prihoda

Prihoda (1983) pages 7-8 presents the power calculations for a two-way design with the following pattern of means:

<table>
<thead>
<tr>
<th>Factor B</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Factor A</td>
<td>1</td>
<td>41</td>
<td>34</td>
<td>30</td>
<td>27</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>33</td>
<td>24</td>
<td>22</td>
<td>29</td>
</tr>
<tr>
<td>All</td>
<td>37</td>
<td>29</td>
<td>26</td>
<td>28</td>
<td>30</td>
</tr>
</tbody>
</table>

The means may be manipulated to show the overall mean, the main effects, and the interaction effects:

<table>
<thead>
<tr>
<th>Factor B</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Factor A</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>-4</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>-1</td>
<td>-2</td>
<td>-1</td>
<td>4</td>
</tr>
<tr>
<td>All</td>
<td>7</td>
<td>-1</td>
<td>-4</td>
<td>-2</td>
<td>30</td>
</tr>
</tbody>
</table>

Based on the above effects, Prihoda calculates the power of the interaction test when the sample size per cell is 6, 8, 10, 12, and 14 to be 0.34, 0.45, 0.56, 0.65, and 0.73. The mean square error is 64 and the alpha level is 0.05.

Setup

Standard Deviation of Subjects = 8.000

Prihoda only presents the power for the interaction test at each sample size. You can check to see that the results match Prihoda’s exactly.
Example 6 - Validation using Neter, Kutner, Nachtsheim, and Wasserman

Neter, Kutner, Nachtsheim, and Wasserman (1996) page 1057 presents a power analysis of a two-factor experiment in which factor A has three levels and factor B has two levels. The significance level is 0.05, the standard deviation is 3.0, and N is 2. They calculate a power of about 0.89 for the test of factor A when the three means are 50, 55, and 45.

Chapter 560

Randomized Block Analysis of Variance

Introduction

This module analyzes a randomized block analysis of variance with up to two treatment factors and their interaction. It provides tables of power values for various configurations of the randomized block design.

The Randomized Block Design

The randomized block design (RBD) may be used when a researcher wants to reduce the experimental error among observations of the same treatment by accounting for the differences among blocks. If three treatments are arranged in two blocks, the RBD might appear as follows:

<table>
<thead>
<tr>
<th>Block A</th>
<th>Block B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Treatment 1</td>
<td>Treatment 2</td>
</tr>
<tr>
<td>Treatment 3</td>
<td>Treatment 1</td>
</tr>
<tr>
<td>Treatment 2</td>
<td>Treatment 3</td>
</tr>
</tbody>
</table>

This diagram shows the main features of a RBD:
1. Each block is divided into \( k \) subblocks, where \( k \) is the number of treatments.
2. Each block receives all the treatments.
3. The treatments are assigned to the subblocks in random order.
4. There is some reason to believe that the blocks are the same internally, but different from each other.

RBD Reduces Random Error

The random error component of a completely randomized design (such as a one-way or a fixed-effects factorial design) represents the influence of all possible variables in the universe on the response except for the controlled (treatment) variables. This random error component is called the standard deviation or \( \sigma \) (sigma).
As we have discussed, the sample size required to meet alpha and beta error requirements depends directly on the standard deviation. As the standard deviation increases, the sample size increases. Hence, researchers are always looking for ways to reduce the standard deviation. Since the random error component contains the variation due to all possible variables other than treatment variables, one of the most obvious ways to reduce the standard deviation is to remove one or more of these *nuisance* variables from the random error component. One of the simplest ways of doing this is by blocking on them.

For example, an agricultural experiment is often blocked on fields so that differences among fields are explicitly accounted for and removed from the error component. Since these field differences are caused by variations in variables such as soil type, sunlight, temperature, and water, blocking on fields removes the influence of several variables.

Blocks are constructed so that the response is as alike (homogeneous) as possible within a block, but as different as possible between blocks. In many situations, there are obvious natural blocking factors such as schools, seasons, individual farms, families, times of day, etc. In other situations, the blocks may be somewhat artificially constructed.

Once the blocks are defined, they are divided into $k$ smaller sections called *subblocks*, where $k$ is the number of treatment levels. The $k$ treatments are randomly assigned to the subblocks, one block at a time. Hence the order of treatment application will be different from block to block.

### Measurement of Random Error

The measurement of the random error component ($\sigma$) is based on the assumption that there is no fundamental relationship between the treatment variable and the blocking variable. When this is true, the interaction component between blocks and treatment is zero. If the interaction component is zero, then the amount measured by the interaction is actually random error and can be used as an estimate of $\sigma$.

Hence, the randomized block design makes the assumption that there is no interaction between treatments and blocks. The block by treatment mean square is still calculated, but it is used as the estimated standard deviation. This means that the degrees of freedom associated with the block-treatment interaction are the degrees of freedom of the error estimate. If the experimental design has $k$ treatments and $b$ blocks, the interaction degrees of freedom are equal to $(k-1)(b-1)$. Hence the sample size of this type of experiment is measured in terms of the number of blocks.

### Treatment Effects

Either one or two treatment variables may be specified. If two are used, their interaction may also be measured. The null hypothesis in the $F$ test states that the effects of the treatment variable are zero. The magnitude of the alternative hypothesis is represented as the size of the standard deviation ($\sigma_m$) of these effects. The larger the size of the effects, the larger their standard deviation.

When there are two factors, the block-treatment interaction may be partitioned just as the treatment may be partitioned. For example, if we let $C$ and $D$ represent two treatments, an analysis of variance will include the terms $C$, $D$, and $CD$. If we represent the blocking factor as $B$, there will be three interactions with blocks: $BC$, $BD$, and $BCD$. Since all three of these terms are assumed to measure the random error, the overall estimate of random error is found by averaging (or pooling) these three interactions. The pooling of these interactions increases the power of the experiment by effectively increasing the sample size on which the estimate of $\sigma$ is based. However, it is based on the assumption that $\sigma = \sigma_{BC} = \sigma_{BD} = \sigma_{BCD}$, which may or may not be true.
An Example

Following is an example of data from a randomized block design. The block factor has four blocks \( (B1, B2, B3, B4) \) while the treatment factor has three levels (low, medium, and high). The response is shown within the table.

<table>
<thead>
<tr>

</tbody>
</table>

Analysis of Variance Hypotheses

The \( F \) test for treatments in a randomized block design tests the hypothesis that the treatment effects are zero. (See the beginning of the Fixed-Effects Analysis of Variance chapter for a discussion of the meaning of effects.)

Single-Factor Repeated Measures Designs

The randomized block design is often confused with a single-factor repeated measures design because the analysis of each is similar. However, the randomization pattern is different. In a randomized block design, the treatments are applied in random order within each block. In a repeated measures design, however, the treatments are usually applied in the same order through time. You should not mix the two. If you are analyzing a repeated measures design, we suggest that you use that module of \textit{PASS} to do the sample size and power calculations.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data and Reports tabs. To find out more about using the other tabs, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Terms (A, B, and AB)

These check boxes specify which terms are included in the analysis of variance model. Check a term to indicate that it is included.

The two factors are assigned the labels $A$ and $B$. The interaction between factors $A$ and $B$ is labeled $AB$. You cannot include the interaction term without including both $A$ and $B$.

Categories (A and B)

This option specifies the number of categories (levels) contained in each factor. Since the effective sample size is equal to the product of the number of levels in each factor and the number of blocks, increasing the number of levels of a factor increases the sample size of the experiment.

Hypothesized Means (A and B)

Enter a set of hypothesized means (or effects), one for each factor level. The standard deviation of these means is used in the power calculations. The standard deviation is calculated using the formula:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - \overline{e})^2}{k}}$$

where $k$ is the number of levels. Note that the standard deviation will be the same whether you enter means or effects since the average of the effects is zero by definition.

Enter a set of means that give the pattern of differences you expect or the pattern that you wish to detect. For example, in a particular study involving a factor with three categories, your research might be meaningful if either of two treatment means is 50% larger than the control mean. If the control mean is 50, then you would enter 50, 75, 75 as the three means.

It is usually more intuitive to enter a set of mean values. However, it is possible to enter the standard deviation of the means directly by placing an $S$ in front of the number.
**Entering a list of means**

If numbers are entered without a leading $S$, they are assumed to be the hypothesized group means under the alternative hypothesis. Their standard deviation will be calculated and used in the calculations. Blanks or commas may separate the numbers. Note that it is not the values of the means themselves that is important, but only their differences. Thus, the mean values 0,1,2 produce the same results as the values 100,101,102.

If not enough means are entered to match the number of groups, the last mean is repeated. For example, suppose that four means are needed and you enter 1,2 (only two means). **PASS** will treat this as 1,2,2,2. If too many values are entered, **PASS** will truncate the list to the number of means needed.

Examples:

5 20 60
2,5,7
-4,0,6,9

**S Option**

If an $S$ is entered before a number, the number is assumed to be the value of $\sigma_m$, the standard deviation of the means.

Examples:

S 4.6
S 5.8

**Hypothesized Effects**

Specify the standard deviation of the interaction effects using one of the following methods:

1. Enter a set of effects and let the program calculate their standard deviation.
2. Enter the standard deviation directly.
3. Instruct the program to make the standard deviation proportional to one of the main effect terms.

The standard deviation of the effects is calculated using the formula:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - \bar{e})^2}{k}}$$

where $k$ is the number of effects and $e_1, e_2, \ldots, e_k$ are the effect values. The value of $\bar{e}$ may be ignored because it is zero by definition.
Syntax

Entering a list of effects
If numbers are entered without a leading letter, they are assumed to be the hypothesized effects under the alternative hypothesis (they are all assumed to be zero under the null hypothesis). Their standard deviation will be calculated and used in the calculations. Blanks or commas may separate the numbers.

If not enough effects are entered to match the number of levels in the term, the last effect is repeated. For example, suppose that four effects are needed and you enter 1,2 (only two effects). \textit{PASS} will treat this as 1,2,2,2. If too many values are entered, \textit{PASS} will truncate the list to the number of effects needed.

For interactions, the number of effects is equal to the product of the number of levels of each factor in the interaction. For example, suppose a two-factor design has one factor with three levels and another factor with five levels. The number of effects in the two-factor interaction is (3)(5) = 15.

Examples (note that they sum to zero):
-1 1 -3 3
2 2 0 -1 -1 -2
-4,0,1,3

S Option
If an \textit{S} is followed by a number, the number is assumed to be the value of $\sigma_m$, the standard deviation of the effects.

When a set of effects are equal to either $e$ or $-e$, the formula for the standard deviation may be simplified as follows:

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^{k} (e_i - \bar{e})^2}{k}}$$

Hence, another interpretation of $\sigma_m$ is the absolute value of a set of effects that are equal, except for the sign.

Example:
\textit{S} 4.7
**Enter a Term Followed by a Percentage**

You can enter the name of a previous term followed by a percentage. This instructs the program to set this standard deviation to \( x \% \) of the term you specify, where \( x \) is a positive integer. This allows you to set the magnitude of the interaction standard deviation as a percentage of the standard deviation of one of the factors without specifying the interaction in detail.

For example, if the standard deviation of factor \( A \) is 16, the command

\[ A \ 75 \]

will set the standard deviation of the current term to \((16)(75)/(100) = 12.0\).

Other examples of this syntax are:

\[ A \ 50 \]
\[ B \ 25 \]

**Discussion**

The general formula for the calculation of the standard deviation is

\[
\sigma_m = \sqrt{\frac{1}{k} \sum e_i^2}
\]

where \( k \) is the number of effects. In the case of a two-way interaction, the standard deviation is calculated using the formula:

\[
\sigma_m(AB) = \sqrt{\frac{\sum_{i=1}^{I} \sum_{j=1}^{J} (\mu_{ij} - \mu_{i\bullet} - \mu_{\bullet j} + \bar{\mu})^2}{IJ}}
\]

where \( i \) is the factor \( A \) index (from 1 to \( I \)), \( j \) is the factor \( B \) index (from 1 to \( J \)), \( \mu_{ij} \) is the mean in the \( ij^{th} \) cell, \( \mu_{i\bullet} \) is the \( i^{th} \) mean of factor \( A \) across all levels of other factors, \( \mu_{\bullet j} \) is the \( j^{th} \) mean when factor \( B \) across all levels of other factors, and \( \bar{\mu} \) is the overall mean of the means.

To see how this works, consider the following table of means from an experiment with \( I = 2 \) and \( J = 3 \):

<table>
<thead>
<tr>
<th>( i )</th>
<th>1</th>
<th>2</th>
<th>---</th>
<th>---</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.0</td>
<td>4.0</td>
<td>3.0</td>
<td>3.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>6.0</td>
<td>5.0</td>
<td>5.0</td>
</tr>
<tr>
<td>3</td>
<td>6.0</td>
<td>11.0</td>
<td>8.5</td>
<td>8.5</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Total</td>
<td>4.0</td>
<td>7.0</td>
<td>5.5</td>
<td>5.5</td>
</tr>
</tbody>
</table>
Now, if we subtract the factor $A$ means, subtract the factor $B$ means, and add the overall mean, we get the interaction effects:

\[
\begin{array}{cc}
0.5 & -0.5 \\
0.5 & -0.5 \\
-1.0 & 1.0 \\
\end{array}
\]

Next, we sum the squares of these six values:

\[
(0.5)^2 + (-0.5)^2 + (0.5)^2 + (-0.5)^2 + (-1.0)^2 + (1.0)^2 = 3
\]

Next we divide this value by $(2)(3) = 6$:

\[
\frac{3}{6} = 0.5
\]

Finally, we take the square root of this value:

\[
\sqrt{0.5} = 0.7071
\]

Hence, for this configuration of means,

\[
\sigma_m(AB) = 0.7071.
\]

Notice that the average of the absolute values of the interaction effects is:

\[
\frac{0.5 + 0.5 + 0.5 + 0.5 + 1.0 + 1.0}{6} = 0.6667.
\]

We see that SD(interaction) is close to the average absolute interaction effect. That is, 0.7071 is close to 0.6667. This will usually be the case. Hence, one way to interpret the interaction standard deviation is as a number a little larger than the average absolute interaction effect.

**Alpha**

This option specifies the probability of a type-I error (alpha) for each term. A type-I error occurs when you reject the null hypothesis that the effects are zero when in fact they are.

Since they are probabilities, alpha values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This value may be interpreted as meaning that about one $F$ test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

You can select different alpha values for different terms. For example, although you have three factors in an experiment, you might be mainly interested in only one of them. Hence, you could increase the alpha level of the tests from, for example, 0.05 to 0.10 and thereby increase their power. Also, you may want to increase the alpha level of the interaction terms, since these will often have poor power otherwise.
Number of Blocks
This specifies one or more values for the number of blocks. If a list of values is entered, a separate calculation will be made for each value.

S (Standard Deviation)
This option specifies the value of the standard deviation. In a randomized block design, this value is estimated by the square root of the mean square error (which may be listed as the mean square of the block-by-treatment interaction). This value will usually have to be determined from a previous study.

Assuming that each block is divided into several subblocks, this is an estimate of the standard deviation that would result when the subblocks within the same block received the same treatment.

If you want to use the effect size, $f$, as the measure of the variability of the effects, you can use 1.0 for $\sigma$.

Estimating the standard deviation is discussed in detail in the Sigma Calculator chapter.
Example1 - Power after a study

This example will explain how to calculate the power of $F$ tests from data that have already been collected and analyzed.

We will analyze the power of the experiment that was given at the beginning of this chapter.

These data were analyzed using the analysis of variance procedure in NCSS and the following results were obtained.

<table>
<thead>
<tr>

<td>8.33334E-02</td>
</tr>
</tbody>
</table>

We will now calculate the power of the $F$ test. Note that factor $B$ in this printout becomes factor $A$ on the PASS template.

Setup

To analyze these data, we enter the means for factor $A$. The value of $\sigma$ is estimated as the square root of the mean square error:

$$\sigma = \sqrt{1.138889} = 1.0672$$

You can enter these values yourself or load the Example1 template from the Template tab.

Standard Deviation Within Blocks (block-treatment interaction) = 1.067

Summary Statements
A randomized-block design with one treatment factor at 3 levels has 2.0 blocks each with 3.0 treatment combinations. The square root of the block-treatment interaction is 1.067. This design achieves 42% power when an F test is used to test factor A at a 5% significance level and the actual standard deviation among the appropriate means is 1.940 (an effect size of 1.8179).

This report shows the power for each of the five block counts. We see that adequate power of about 0.9 would have been achieved by three blocks.

It is important to emphasize that these power values are for the case when the effects associated with the alternative hypotheses are equal to those given by the data. It will often be informative to calculate the power for other values as well.

Term
This is the term (main effect or interaction) from the analysis of variance model being displayed on this line.

Power
This is the power of the F test for this term. Note that since adding and removing terms changes the denominator degrees of freedom (df2), the power depends on which other terms are included in the model.

Blocks
This is the number of blocks in the design.

Units
This is the number of subblocks (plots) in the design. It is the product of the number of treatment levels and the number of blocks.

df1
This is the numerator degrees of freedom of the F test.

df2
This is the denominator degrees of freedom of the F test. This value depends on which terms are included in the AOV model.
**Std Dev of Means (Sm)**
This is the standard deviation of the means (or effects). It represents the size of the differences among the effects that is to be detected by the analysis. If you have entered hypothesized means, only their standard deviation is displayed here.

**Effect Size**
This is the standard deviation of the means divided by the standard deviation of subjects. It provides an index of the magnitude of the difference among the means that can be detected by this design.

**Alpha**
This is the significance level of the $F$ test. This is the probability of a type-I error given the null hypothesis of equal means and zero effects.

**Beta**
This is the probability of the type-II error for this test given the sample size, significance level, and effect size.
Example2 - Validation with Prihoda

Prihoda (1983) presents details of an example that is given in Odeh and Fox (1991). In this example, Alpha is 0.025, Sm of A is 0.577, the number of treatments in factor A is 6, the number of treatments in factor B is 3, S is 1.0, and the Number of Blocks is 2, 3, 4, 5, 6, 7, and 8. Prihoda gives the power values for the $F$ test on factor A as 0.477, 0.797, 0.935, 0.982, 0.995, 0.999, and 1.000.

You can enter these values yourself or load the Example2 template from the Template tab.

Standard Deviation Within Blocks (block-treatment interaction) = 1.00

We have bolded the power values on this report that should match Prihoda’s results. You see that they do match.
Chapter 570

Repeated Measures Analysis of Variance

Introduction

This module calculates the power for repeated measures designs having up to three within factors and up to three between factors. It computes power for various test statistics including the $F$ test with the Geisser-Greenhouse correction, Wilks’ lambda, Pillai-Bartlett trace, and Hotelling-Lawley trace. It can be used to calculate the power of crossover designs.

Repeated measures designs are popular because they allow a subject to serve as their own control. This usually improves the precision of the experiment. However, when the analysis of the data uses the traditional $F$ tests, additional assumptions concerning the structure of the error variance must be made. When these assumptions do not hold, the Geisser-Greenhouse correction provides reasonable adjustments so that significance levels are accurate.

An alternative to using the $F$ test with repeated measures designs is to use one of the multivariate tests: Wilks’ lambda, Pillai-Bartlett trace, or Hotelling-Lawley trace. These alternatives are appealing because they do not make the strict, often unrealistic, assumptions about the structure of the error variance. Unfortunately, they may have less power than the $F$ test and they cannot be used in all situations.

An example of a two-factor repeated measures design that can be analyzed by this procedure is shown by the following diagram.

<table>
<thead>
<tr>
<th>Group 1</th>
<th>Month</th>
<th>Group 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject 1</td>
<td>Subject 2</td>
<td>1</td>
</tr>
<tr>

</tr>
<tr>
<td>Treatment M</td>
<td>Treatment M</td>
<td>Treatment M</td>
</tr>
<tr>
<td>Treatment H</td>
<td>Treatment H</td>
<td>Treatment H</td>
</tr>
</tbody>
</table>

Groups 1 and 2 form the between factor. The within factor has three levels: $L$, $M$, and $H$ (low, medium, and high). There are four subjects in this experiment. The three treatments are applied to each subject, one treatment per month. Note that the three treatments are applied to each subject in the same order. Although the order of treatment application should be randomized, it is often the same for all subjects.

This diagram shows the main features of a repeated measures design, which are
1. Each subject receives all treatments.
2. The treatments are applied through time. When the treatments are applied in the same order across all subjects, it is impossible to separate the treatment effects from the sequence effects. Some processes that can cause sequence effects are learning, practice, or fatigue—any pattern in the responses across time that occurs without the treatment. If you think the possibility for sequence effects exists, you must make sure that the effects of prior treatments have been washed out before applying the next treatment.
3. Unlike other designs, the repeated measures design has two experimental units: between and within. In this example, the first (between) experimental unit is a subject. Subject-to-subject variability is used to test the between factor (groups). The second (within) experimental unit is the time period. In the above example, the month to month variability within a subject is used to test the treatment. The important point to realize is that the repeated measures design has two error components, the between and the within.

**Assumptions**
The following assumptions are made when using the $F$ test to analyze a factorial experimental design.

1. The response variable is continuous.
2. The residuals follow the normal probability distribution with mean equal to zero and constant variance.
3. The subjects are independent. Since in a within-subject design responses coming from the same subject are not independent, assumption 3 must be modified for responses within a subject. Independence between subjects is still assumed.
4. The within-subject covariance matrices are equal for all between-subject groups. In this type of experiment, the repeated measurements on a subject may be thought of as a multivariate response vector having a certain covariance structure. This assumption states that these covariance matrices are constant from group to group.
5. When using an $F$ test, the within-subject covariance matrices are assumed to be circular. One way of defining circularity is that the variances of differences between any two measurements within a subject are constant for all measurements. Since responses that are close together in time often have a higher correlation than those that are far apart, it is common for this assumption to be violated. This assumption is not necessary for the validity of the three multivariate tests: Wilks’ lambda, Pillai-Bartlett trace, or Hotelling-Lawley trace.

**Advantages of Within-Subjects Designs**
Because the response to stimuli usually varies less within an individual than between individuals, the within-subject variability is usually less than (or at most equal to) the between-subject variability. By reducing the underlying variability, the same power can be achieved with a smaller number of subjects.

**Disadvantages of Within-Subjects Designs**
1. Practice effect. In some experiments, subjects systematically improve as they practice the task being studied. In other cases, subjects may systematically get worse as they get fatigued or bored with the experimental task. Note that only the treatment administered first is immune to practice effects. Hence, experimenters should make an effort to balance the number of subjects receiving each treatment first.
2. *Carryover effect.* In many drug studies, it is important to wash out the influence of one drug completely before the next drug is administered. Otherwise, the influence of the first drug carries over into the response to the second drug.

3. *Statistical analysis.* The statistical model is more restrictive than in a regular factorial design since the individual responses must have certain mathematical properties.

Even in the face of all these disadvantages, repeated measures (within-subject) designs are popular in many areas of research. It is important that you recognize these problems going in so you can make sure that the design is appropriate, rather than learning of them later after the research has been conducted.

**Technical Details**

**General Linear Multivariate Model**

This section provides the technical details of the repeated measures designs that can be analyzed by PASS. The approximate power calculations outlined in Muller, LaVange, Ramey, and Ramey (1992) are used. Using their notation, for $N$ subjects, the usual general linear multivariate model is

\[ Y = XM + R \]

where each row of the residual matrix $R$ is distributed as a multivariate normal

\[ \text{row}_k(R) \sim N_p(0, \Sigma) \]

Note that $p$ is the product of the number of levels of each of the within-subject factors, $q$ is the number of design variables, $Y$ is the matrix of responses, $X$ is the design matrix, $M$ is the matrix of regression parameters (means), and $R$ is the matrix of residuals.

Hypotheses about various sets of regression parameters are tested using

\[ H_0: \Theta = \Theta_0 \]

\[ CMD \times q \times \times b = \Theta \]

where $C$ and $D$ are orthonormal contrast matrices and $\Theta_0$ is a matrix of hypothesized values, usually zeros. Note that $C$ defines contrasts among the between-subject factor levels and $D$ defines contrast among the within-subject factor levels.
Tests of the various main effects and interactions may be constructed with suitable choices for $C$ and $D$. These tests are based on

$$
\tilde{M} = (X' X)^{-} X' Y
$$
$$
\hat{\Theta} = CMD
$$
$$
H_{b \times b} = \left(\hat{\Theta} - \Theta_0\right)' \left[C(X' X)^{-} C\right]^{-1} \left(\hat{\Theta} - \Theta_0\right)
$$
$$
E_{b \times b} = D' \hat{\Sigma} D \cdot (N-r)
$$
$$
T = H + E
$$

where $r$ is the rank of $X$.

**Geisser-Greenhouse F Test**

Upon the assumption that $\Sigma$ has compound symmetry, a size $\alpha$ test of $H_0: \Theta = \Theta_0$ is given by the $F$ ratio

$$
F = \frac{\text{tr}(H)/ab}{\text{tr}(E)/(b(N-r))}
$$

with degrees of freedom given by

$$
df_1 = ab
$$
$$
df_2 = b(N-r)
$$

and noncentrality parameter

$$
\lambda = df_1(F)
$$

The assumption that $\Sigma$ has compound symmetry is usually not viable. Box (1954a,b) suggested that adjusting the degrees of freedom of the above $F$-ratio could compensate for the lack of compound symmetry in $\Sigma$. His adjustment has become known as the Geisser-Greenhouse adjustment. Under this adjustment, the modified degrees of freedom and noncentrality parameter are given by

$$
df_1 = ab \epsilon
$$
$$
df_2 = b(N-r) \epsilon
$$
$$
\lambda = df_1(F) \epsilon
$$

where

$$
\epsilon = \frac{\text{tr}(D' \hat{\Sigma} D)^2}{b \text{tr}(D' \hat{\Sigma} D D' \hat{\Sigma} D)}
$$

The range of $\epsilon$ is $\frac{1}{b-1}$ to 1. When $\epsilon = 1$, the matrix is spherical. When $\epsilon = \frac{1}{b-1}$, the matrix differs maximally from sphericity.
Note that the Geisser-Greenhouse adjustment is only needed for testing main effects and interactions involving within-subject factors. Main effects and interactions that involve only between-subject factors need no such adjustment.

The critical value $F_{\text{Crit}}$ is computed using the expected value of $\varepsilon$ to adjust the degrees of freedom. That is, the degrees of freedom of $F_{\text{Crit}}$ are given by

$$
\frac{df}{1} = abE(\varepsilon) \\
\frac{df}{2} = b(N - r)E(\varepsilon)
$$

where

$$
E(\hat{\varepsilon}) = \begin{cases} 
\varepsilon + \frac{g_1}{N - r} & \text{if } \varepsilon > \frac{g_1}{N - r} \\
\varepsilon / 2 & \text{otherwise}
\end{cases}
$$

$$
g_i = \sum_{i=1}^{r} f_{ii} \xi_i^2 + \sum_{i \neq j} \frac{f_{ij} \xi_i \xi_j}{\xi_i - \xi_j}
$$

$$
f_i = \frac{\partial \hat{\varepsilon}}{\partial \xi_i^2} \\
= \frac{2 \sum \xi_j}{df_i \sum \xi_j^2} - \frac{2 \lambda_i (\sum \xi_j)^2}{df_i (\sum \xi_j^2)^2}
$$

$$
f_{ii} = \frac{\partial^2 \hat{\varepsilon}}{\partial \xi_i^2^2} \\
= 2h_1 - 8h_2 + 8h_3 - 2h_4
$$

$$
h_1 = \frac{2}{df_i \sum \xi_j^2} \\
h_2 = \frac{\xi_i (\sum \xi_j)}{df_i (\sum \xi_j^2)^2} \\
h_3 = \frac{\xi_i^2 (\sum \xi_j^2)}{df_i (\sum \xi_j^2)^3} \\
h_4 = \frac{(\sum \xi_j)}{df_i (\sum \xi_j^2)^2}
$$

where the $\xi_i$'s are the ordered eigenvalues of $D' \Sigma D$. 

**Wilks’ Lambda Approximate F Test**

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using Wilks’ likelihood ratio statistic $W$. This statistic is computed using

$$ W = \left| E T^{-1} \right| $$

An $F$ approximation to the distribution of $W$ is given by

$$ F_{df_1,df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2} $$

where

$$ \lambda = df_1 F_{df_1,df_2} $$

$$ \eta = 1 - W^{1/2} $$

$$ df_1 = ab $$

$$ df_2 = g \left[ (N - r) - (b - a + 1) / 2 \right] - (ab - 2) / 2 $$

$$ g = \left( \frac{a^2 b^2 - 4}{a^2 + b^2 - 5} \right)^{1/2} $$

**Pillai-Bartlett Trace Approximate F Test**

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using the Pillai-Bartlett Trace. This statistic is computed using

$$ T_{PB} = tr \left( HT^{-1} \right) $$

A noncentral $F$ approximation to the distribution of $T_{PB}$ is given by

$$ F_{df_1,df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2} $$

where

$$ \lambda = df_1 F_{df_1,df_2} $$

$$ \eta = \frac{T_{PB}}{s} $$

$$ s = \min(a,b) $$

$$ df_1 = ab $$

$$ df_2 = s \left[ (N - r) - b + s \right] $$
Hotelling-Lawley Trace Approximate F Test

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using the Hotelling-Lawley Trace. This statistic is computed using

$$T_{HL} = \text{tr}(HE^{-1})$$

An $F$ approximation to the distribution of $T_{HL}$ is given by

$$F_{df_1,df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2}$$

where

$$\lambda = df_1 F_{df_1,df_2}$$

$$\eta = \frac{T_{HL}}{s}$$

$$s = \min(a,b)$$

$$df_1 = ab$$

$$df_2 = s((N - r) - b + s)$$

M (Mean) Matrix

In the general linear multivariate model presented above, $M$ represents a matrix of regression coefficients. Since you must provide the elements of $M$, we will discuss its meaning in more detail. Although other structures and interpretations of $M$ are possible, in this module we assume that the elements of $M$ are the cell means. The rows of $M$ represent the between-subject categories and the columns of $M$ represent the within-group categories.

The $q$ rows of $M$ represent the $q$ groups into which the subjects can be classified. For example, if a design includes three between-subject factors with 2, 3, and 4 categories, the matrix $M$ would have $2 \times 3 \times 4 = 24$ rows. That is, $q = 24$. Similarly, if a design has three within-subject factors with 3, 3, and 3 categories, the matrix $M$ would have $3 \times 3 \times 3 = 27$ columns. That is, $p = 27$.

Consider now an example in which $q = 3$ and $p = 4$. That is, there are three groups into which subjects can be placed. Each subject is measured four times. The matrix $M$ would appear as follows.

$$M = \begin{bmatrix} \mu_{11} & \mu_{12} & \mu_{13} & \mu_{14} \\ \mu_{21} & \mu_{22} & \mu_{23} & \mu_{24} \\ \mu_{31} & \mu_{32} & \mu_{33} & \mu_{34} \end{bmatrix}$$

For example, the element $\mu_{12}$ is the mean of the second measurement of subjects in the first group. To calculate the power of this design, you would need to specify appropriate values of all twelve means.

As a second example, consider a design with three between-subject factors and three within-subject factors, all of which have two categories. The $M$ matrix for this design would be as follows.
The subscripts for each mean follow the pattern $\mu_{B1B2W1W2W3}$. The first three subscripts indicate the between-subject categories and the second three subscripts indicate the within-subject categories. Notice that the first three subscripts are constant in each row and the second three subscripts are constant in each column.

### Specifying the M Matrix

When computing the power in a repeated measures analysis of variance, the specification of the $M$ matrix is one of your main tasks. The program cannot do this for you. The calculated power is directly related to your choice. So your choice for the elements of $M$ must be selected carefully and thoughtfully. When authorization and approval from a government organization is sought, you should be prepared to defend your choice of $M$. In this section, we will explain how you can specify $M$.

Before we begin, it is important that you have in mind exactly what $M$ is. $M$ is a table of means that represent the size of the differences among the means that you want the study or experiment to detect. That is, $M$ gives the means under the alternative hypothesis. Under the null hypothesis, these means are assumed to be equal. Because of the complexity of the repeated measures design, it is often difficult to choose reasonable values, so PASS will help you. But it is important to remember that you are responsible for these values and that the sample sizes calculated are based on them.

One way to specify the $M$ matrix is to do so directly into the spreadsheet. You might do this if you are calculating the ‘retrospective’ power of a study that has already been completed, or if it is simply easier to write the matrix directly. Usually, however, you will specify the $M$ matrix in portions.

We will begin our discussion of specifying the $M$ matrix with an example. Consider a study of two groups of subjects. Each subject was tested, then a treatment was administered, then the subject was tested again at the ten minute mark, and then tested a third time after sixty minutes. The researchers wanted the sample size to be large enough to detect the following pattern in the means.
### Table of Hypothesized Means

<table>
<thead>
<tr>
<th>Time Period</th>
<th>Group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T0</td>
</tr>
<tr>
<td>A</td>
<td>100</td>
</tr>
<tr>
<td>B</td>
<td>120</td>
</tr>
<tr>
<td>Average</td>
<td>110</td>
</tr>
</tbody>
</table>

To understand how they derived this table, we will perform some basic arithmetic on it.

**Step 1 - Remove the overall mean**

Subtract 125, the overall mean, from each of the individual means.

### Table of Hypothesized Means

**Adjusted for Overall Mean**

<table>
<thead>
<tr>
<th>Time Period</th>
<th>Group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T0</td>
</tr>
<tr>
<td>A</td>
<td>-25</td>
</tr>
<tr>
<td>B</td>
<td>-5</td>
</tr>
<tr>
<td>Average</td>
<td>-15</td>
</tr>
</tbody>
</table>

**Step 2 - Remove the group effect**

Subtract -15 from the first row and 15 from the second row.

### Table of Hypothesized Means

**Adjusted for Group**

<table>
<thead>
<tr>
<th>Time Period</th>
<th>Group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T0</td>
</tr>
<tr>
<td>A</td>
<td>-10</td>
</tr>
<tr>
<td>B</td>
<td>-20</td>
</tr>
<tr>
<td>Total</td>
<td>-15</td>
</tr>
</tbody>
</table>
Step 3 - Remove the time effect

Subtract -15 from the first column, 30 from the second column, and -15 from the third column.

<table>
<thead>
<tr>
<th>Table of Hypothesized Means Adjusted for Group and Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time Period</td>
</tr>
<tr>
<td>Group</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>A</td>
</tr>
<tr>
<td>B</td>
</tr>
<tr>
<td>Effect</td>
</tr>
<tr>
<td>Effect + Overall</td>
</tr>
</tbody>
</table>

This table, called an effects table, lets us see the individual effect of each component of the model. For example, we can see that the hypothesized pattern across time is that T10 is 45 units higher than either endpoint. Similarly, we note that the hypothesized pattern for the two groups is that Group B is 30 units larger than Group A.

Understanding the interaction is more difficult. One interpretation focuses on T10. We note that in Group A the response for T10 is 10 less than expected while in Group B the response for T10 is 10 more than expected.

**Entering this information into PASS**

Rather than enter the individual values into PASS, you can enter the group, time, and interaction effects directly. For this example, you could enter ‘110 140’ or ‘-15 15’ for the hypothesized means of the between factor and ‘110 155 110’ or ‘-15 30 -15’ for the hypothesized means of the within factor. For the interaction, you would enter the six interaction values ‘5 -10 5 -5 10 -5’.

Another way to enter the interaction information would be to indicate that the size of the interaction to be detected is about half that of the group factor or about a third of the time factor. For a complete discussion of the interpretation of various interactions, we suggest that you look at Kirk (1982).
C Matrix for Between-Subject Contrasts

The C matrix is comprised of contrasts that are applied to the rows of $M$. That is, these are between-group contrasts. You do not have to specify these contrasts. They are generated for you. You should understand that a different C matrix is generated for each between-subject term in the model. For example, in the six factor example above, the C matrix that will be generated for testing the between-subject factor B1 is

$$C_{B1} = \begin{bmatrix} -1 & -1 & -1 & -1 & 1 & 1 & 1 \\ \sqrt{8} & \sqrt{8} & \sqrt{8} & \sqrt{8} & \sqrt{8} & \sqrt{8} & \sqrt{8} \end{bmatrix}$$

Note that the divisor $\sqrt{8}$ is used so that the total of the squared elements is one. This is required so that the contrast matrix is **orthonormal**.

When creating a test for B1, the matrix $D$ is created to average across all within-subject categories.

$$D_{B1} = \begin{bmatrix} 1 \\ \sqrt{8} \\ 1 \\ \sqrt{8} \\ 1 \\ \sqrt{8} \\ 1 \end{bmatrix}$$

Generating the C Matrix when there are Multiple Between Factors.

Generating the $C$ matrix when there is more than one between factor is more difficult. We like the method of O’Brien and Kaiser (1985) which we briefly summarize here.

**Step 1.** Write a complete set of contrasts suitable for testing each factor separately. For example, if you have three factors with 2, 3, and 4 categories, you might use

$$\tilde{C}_{B1} = \begin{bmatrix} -1 \\ \sqrt{2} \end{bmatrix}, \quad \tilde{C}_{B2} = \begin{bmatrix} -2 & 1 & 1 \\ \sqrt{6} & \sqrt{6} & \sqrt{6} \end{bmatrix}, \quad \text{and} \quad \tilde{C}_{B3} = \begin{bmatrix} -3 & 1 & 1 \\ \sqrt{12} & \sqrt{12} & \sqrt{12} \\ 0 & -2 & 1 \end{bmatrix}.$$
Step 2. Define appropriate $J_k$ matrices corresponding to each factor. These matrices comprised of one row and $k$ columns whose equal element is chosen so that the sum of its elements squared is one. In this example, we use

$$J_2 = \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix}, \quad J_3 = \begin{bmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix}, \quad J_4 = \begin{bmatrix} \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} \end{bmatrix}$$

Step 3. Create the appropriate contrast matrix using a direct (Kronecker) product of either the $\tilde{C}_{Bi}$ matrix if the factor is included in the term or the $J_i$ matrix when the factor is not in the term. Remember that the direct product is formed by multiplying each element of the second matrix by all members of the first matrix. Here is an example

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \otimes \begin{bmatrix} 1 & 0 & -1 \\ 0 & 2 & 0 \\ -1 & 0 & 3 \end{bmatrix}$$

As an example, we will compute the $C$ matrix suitable for testing factor $B_2$

$$C_{B_2} = J_2 \otimes \tilde{C}_{B_2} \otimes J_4$$

Expanding the direct product results in

$$C_{B_2} = J_2 \otimes \tilde{C}_{B_2} \otimes J_4$$

Similarly, the $C$ matrix suitable for testing interaction $B_2 B_3$ is

$$C_{B_2 B_3} = J_2 \otimes \tilde{C}_{B_2} \otimes \tilde{C}_{B_3}$$

We leave the expansion of this matrix PASS, but we think you have the idea.
D Matrix for Within-Subject Contrasts
The $D$ matrix is comprised of contrasts that are applied to the columns of $M$. That is, these are within-group contrasts. You do not have to specify these contrasts either. They will be generated for you. Specification of the $D$ matrix is similar to the specification of the $C$ matrix, except that now the matrices are all transposed.

Interactions of Between-Subject and Within-Subject Factors
Interactions that include both between-subject factors and within-subject factors require that between-subject portion be specified by the $C$ matrix and the within-subject portion be specified with the $D$ matrix.

Power Calculations
To calculate statistical power, we must determine distribution of the test statistic under the alternative hypothesis which specifies a different value for the regression parameter matrix $B$. The distribution theory in this case has not been worked out, so approximations must be used. We use the approximations given by Mueller and Barton (1989) and Muller, LaVange, Ramey, and Ramey (1992). These approximations state that under the alternative hypothesis, $F_U$ is distributed as a noncentral $F$ random variable with degrees of freedom and noncentrality shown above. The calculation of the power of a particular test may be summarized as follows

1. Specify values of $X, M, \Sigma, C, D,$ and $\Theta_0$.
2. Determine the critical value using $F_{\text{crit}} = \text{FINV}(1 - \alpha, df_1, df_2)$, where $\text{FINV}( )$ is the inverse of the central $F$ distribution and $\alpha$ is the significance level.
3. Compute the noncentrality parameter $\lambda$.
4. Compute the power as
   \[ \text{Power} = 1 - \text{NCFPROB}(F_{\text{crit}}, df_1, df_2, \lambda) \]
   where $\text{NCFPROB}( )$ is the noncentral $F$ distribution.
Covariance Matrix Assumptions

The following assumptions are made when using the $F$ test. These assumptions are not needed when using one of the three multivariate tests.

In order to use the $F$ ratio to test hypotheses, certain assumptions are made about the distribution of the residuals $e_{ijk}$. Specifically, it is assumed that the residuals for each subject, $e_{ij1}, e_{ij2}, \ldots, e_{ijT}$, are distributed as a multivariate normal with means equal to zero and covariance matrix $\Sigma_{ij}$. Two additional assumptions are made about these covariance matrices. First, they are assumed to be equal for all subjects. That is, it is assumed that $\Sigma_{11} = \Sigma_{12} = \cdots = \Sigma_{Gn} = \Sigma$.

Second, the covariance matrix is assumed to have a particular form called circularity. A covariance matrix is circular if there exists a matrix $A$ such that

$$\Sigma = A + A' + \lambda I_T$$

where $I_T$ is the identity matrix of order $T$ and $\lambda$ is a constant.

This property may also be defined as

$$\sigma_{ii} + \sigma_{jj} - 2\sigma_{ij} = 2\lambda$$

One type of matrix that is circular is one that has compound symmetry. A matrix with this property has all elements on the main diagonal equal and all elements off the main diagonal equal. An example of a covariance matrix with compound symmetry is

$$\Sigma = \begin{bmatrix}
\sigma^2 & \rho\sigma^2 & \rho\sigma^2 & \cdots & \rho\sigma^2 \\
\rho\sigma^2 & \sigma^2 & \rho\sigma^2 & \cdots & \rho\sigma^2 \\
\rho\sigma^2 & \rho\sigma^2 & \sigma^2 & \cdots & \rho\sigma^2 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\rho\sigma^2 & \rho\sigma^2 & \rho\sigma^2 & \cdots & \sigma^2 
\end{bmatrix}$$

or, with actual numbers,

$$\begin{bmatrix}
9 & 2 & 2 & 2 \\
2 & 9 & 2 & 2 \\
2 & 2 & 9 & 2 \\
2 & 2 & 2 & 9 
\end{bmatrix}$$

An example of a matrix which does not have compound symmetry but is still circular is

$$\begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & 2 & 2 & 2 \\
2 & 1 & 3 & 3 \\
3 & 2 & 3 & 4 \\
4 & 3 & 2 & 4 \\
1 & 2 & 3 & 4 \\
2 & 1 & 2 & 3 \\
0 & 2 & 0 & 0 \\
0 & 0 & 2 & 0 \\
0 & 0 & 0 & 2 \\
4 & 3 & 4 & 5 \\
3 & 6 & 5 & 6 \\
4 & 5 & 8 & 7 \\
5 & 6 & 7 & 10 
\end{bmatrix}$$

Needless to say, the need to have the covariance matrix circular is a very restrictive assumption.
Between Standard Deviation

The subject-to-subject variability is represented by $\sigma^2_{\text{Between}}$. In the repeated measures AOV table, this quantity is estimated by the between subjects mean square ($MSB$). This quantity is calculated from $\Sigma$ using the formula

$$\sigma^2_{\text{Between}} = \frac{\sum_{i=1}^{T} \sum_{j=1}^{T} \sigma_{ij}}{T} = \frac{\sum_{i=1}^{T} \sum_{j=1}^{T} \sigma_{ij} \rho_{ij}}{T}$$

When $\Sigma$ has compound symmetry, which requires all $\sigma_{ii} = \sigma$ and all $\rho_{ij} = \rho$, the above formula reduces to

$$\sigma^2_{\text{Between}} = \sigma^2(1 + (T - 1)\rho)$$

Note that $F$ tests of between factors and their interactions do not require the circularity assumption so the Geisser-Greenhouse correction is not applied to these tests.

Within Standard Deviation

The within-subject variability is represented by $\sigma^2_{\text{Within}}$. In the repeated measures AOV table, this quantity is estimated by the within-subjects mean square ($MSW$). This quantity is calculated from $\Sigma$ using the formula

$$\sigma^2_{\text{Within}} = \frac{\sum_{i=1}^{T} \sigma_{ii}}{T} - \frac{2 \sum_{i=1}^{T} \sum_{j=i+1}^{T} \sigma_{ij}}{T(T-1)} \sqrt{\frac{\sigma_{ii} \sigma_{jj}}{T(T-1)}}$$

When $\Sigma$ has compound symmetry, which requires all $\sigma_{ii} = \sigma$ and all $\rho_{ij} = \rho$, the above formula reduces to

$$\sigma^2_{\text{Within}} = \sigma^2(1 - \rho)$$
Estimating Sigma and Rho from Existing Data

Using the above results for existing data, approximate values for \( \sigma \) and \( \rho \) may be estimated from a previous analysis of variance table that provides estimates of MSB and MSW. Solving the above equations for \( \sigma \) and \( \rho \) yields

\[
\rho = \frac{\sigma_{\text{Between}}^2 - \sigma_{\text{Within}}^2}{\sigma_{\text{Between}}^2 + (T - 1)\sigma_{\text{Within}}^2}
\]

\[
\sigma^2 = \frac{\sigma_{\text{Within}}^2}{1 - \rho}
\]

Substituting MSB for \( \sigma_{\text{Between}}^2 \) and MSW for \( \sigma_{\text{Within}}^2 \) yields the estimates

\[
\hat{\rho} = \frac{\text{MSB} - \text{MSW}}{\text{MSB} + (T - 1)\text{MSW}}
\]

\[
\hat{\sigma}^2 = \frac{\text{MSW}}{1 - \hat{\rho}}
\]

Note that these estimators assume that the design meets the circularity assumption, which is usually not the case. However, they provide crude estimates that can be used in planning.
Procedure Options

This section describes the options that are unique to this procedure. To find out more about using the other tabs, turn to the chapter entitled Procedure Templates.

Data 1 & 2 Tabs

The Data tab contains most of the parameters and options that you will be concerned with.

Find (Solve For)

This option specifies the parameter to be solved for. If you choose to solve for \( n \) (sample size), you must also specify which test statistic you want to use.

When you choose to solve for \( n \), the program searches for the lowest sample size that meets the alpha and beta criterion you have specified for each of the terms. If you do not want a term to be used in the search, set its alpha and beta values to 0.99.

Also, when the ‘= n’s’ box is not checked, the search is made using unequal group sample sizes. The relative proportion of the sample in each group is set by the values of \( n \) given in the Subjects Per Group box. For example, if your design has three groups and you entered ‘1 1 2’ in the Subjects Per Group box, the search will only consider designs in which the size of the last group is twice the rest. That is, it will consider ‘2 2 4’, ‘3 3 6’, ‘4 4 8’, etc.

Note: no plots are generated when you solve for \( n \).

\( n \) (Subjects Per Group)

Specify one or more values for the number of subjects per group. The total sample size is the sum of the individual group sizes across all groups.

You can specify a list like ‘2 4 6’. The items in the list may be separated with commas or blanks. The interpretation of the list depends on the =n's check box. When the =n's box is checked, a separate analysis is calculated for each value of \( n \). When the =n's box is not checked, PASS uses the \( n ' s \) as the actual group sizes. In this case, the number of items entered must match the number of groups in the design.

When you choose to solve for \( n \) and the ‘= n’s’ box is not checked, the search is made using unequal group sample sizes. The relative proportion of the sample in each group is set by the values of \( n \) given in this box. For example, if your design has three groups and you enter ‘1 1 2’ here, the search will only consider designs in which the size of the last group is twice the rest. That is, it will consider ‘2 2 4’, ‘3 3 6’, ‘4 4 8’, etc.

= n’s

This option controls whether the number of subjects per group is to be equal for all groups or not. When checked, the number of subjects per group is equal for all groups. A list of values such as ‘5 10 15’ represents three designs: one with five per group, one with ten per group, and one with fifteen per group.

When this option is not checked, the n’s are assumed to be unequal. A list of values represents the size of the individual groups. For example, ‘5 10 15’ represents a single, three-group design with five in the first group, ten in the second group, and fifteen in the third group.
Means Matrix

Use this option to specify spreadsheet columns containing a hypothesized means matrix that will be used to compute the Sm values. All individual Sm values are ignored. You can obtain the spreadsheet by selecting ‘Window’, then ‘Data’, from the menus.

The between factors are represented across the columns of the spreadsheet and the within factors are represented down the rows. The number of columns specified must equal the number of groups. The number of rows with data in these columns must equal the number of times. For example, suppose you are designing an experiment that is to have two between factors (A & B) and two within factors (D & E). Suppose each of the four factors has two levels. The columns of the spreadsheet would be

The rows of the spreadsheet would represent

D1E1
D1E2
D2E1
D2E2

Example

To see how this option works, consider the following table of hypothesized means for an experiment with one between factor (A) having two groups and one within factor (B) having three time periods. The values in columns C1 and C2 of the spreadsheet are

<table>
<thead>
<tr>
<th>C1</th>
<th>C2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0</td>
<td>4.0</td>
</tr>
<tr>
<td>4.0</td>
<td>6.0</td>
</tr>
<tr>
<td>6.0</td>
<td>11.0</td>
</tr>
</tbody>
</table>

By subtracting the appropriate means, the following table of effects results

<table>
<thead>
<tr>
<th>C1</th>
<th>C2</th>
<th>Means</th>
<th>Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.5</td>
<td>-0.5</td>
<td>3.0</td>
<td>-2.5</td>
</tr>
<tr>
<td>0.5</td>
<td>-0.5</td>
<td>5.0</td>
<td>-0.5</td>
</tr>
<tr>
<td>-1.0</td>
<td>1.0</td>
<td>8.5</td>
<td>3.0</td>
</tr>
<tr>
<td>Means</td>
<td>4.0</td>
<td>7.0</td>
<td>5.5</td>
</tr>
<tr>
<td>Effects</td>
<td>-1.5</td>
<td>1.5</td>
<td></td>
</tr>
</tbody>
</table>

The standard deviation of the A effects is calculated as

\[
\sigma_A = \sqrt{\frac{(-1.5)^2 + (1.5)^2}{2}}
\]

\[
= \sqrt{2.25}
\]

\[
= 1.5
\]
The standard deviation of the B effects is calculated as

\[ \sigma_B = \sqrt{\frac{(-2.5)^2 + (-0.5)^2 + (3.0)^2}{3}} \]

\[ = \sqrt{\frac{15.5}{3}} \]

\[ = 2.27 \]

The standard deviation of the interaction effects is found to be

\[ \sigma_{AB} = \sqrt{\frac{(0.5)^2 + (0.5)^2 + (-1.0)^2 + (-0.5)^2 + (0.5)^2 + (1.0)^2}{6}} \]

\[ = \sqrt{\frac{3.0}{6}} \]

\[ = 0.71 \]

These three standard deviations are used to represent the effect sizes of the corresponding terms.

**Discussion**

When using this option, it is less confusing to concentrate on a single term at a time. For example, consider a 2-by-4 design in which your primary interest is in testing the AB interaction. Instead of trying to determine a means matrix that will represent factor A, factor B, and the AB interaction, ignore factor A and factor B and just consider the interaction. You might want to consider the following pattern

\[
\begin{array}{c|c}
C1 & C2 \\
0.0 & 0.0 \\
0.0 & 1.0 \\
0.0 & 2.0 \\
0.0 & 3.0 \\
\end{array}
\]

That is, the first group remains constant while the second group increases for 0.0 to 3.0.

By specifying various values for K (the means multiplier), you can study the impact of increasing the values. For example, when K is set to 2, the above means matrix becomes

\[
\begin{array}{c|c}
C1 & C2 \\
0.0 & 0.0 \\
0.0 & 2.0 \\
0.0 & 4.0 \\
0.0 & 6.0 \\
\end{array}
\]

Thus, by simply changing K, several scenarios may be studied. (We wish to thank Keith Muller for suggesting this method of specifying the Sm values.)
**K (Means Multipliers)**

These values are multiplied times the means matrix to give you various effect sizes. A separate power calculation is generated for each value of K. These values become the horizontal axis in the second power chart. For example, if an Sm value is 80, setting this option to ‘50 100 150’ would result in three Sm values: 40, 80, and 120. If you want to ignore this setting, enter ‘1’.

Note that when you enter Sm values directly, **PASS** generates an appropriate means matrix and then multiplies this matrix by each of these K values.

**Labels**

Specify a label for this factor. Although we suggest that only a single letter be used, the label can consist of several letters. When several letters are used, the labels for the interactions may be extra long and confusing. Of course, you must be careful not to use the same label for two factors.

One of the easiest sets of labels is to use A, B, and C for the between factors and D, E, and F for the within factors. A useful alternative is to use B1, B2, and B3 for the between factors and W1, W2, and W3 for the within factors.

**Levels**

Specify the number of levels (categories) in this factor. Typical values are from 2 to 8. Set this to a blank (or 0) to ignore the factor in the design.

**Alpha**

These options specify the probability of a type-I error (alpha) for each factor and interaction. A type-I error occurs when you reject the null hypothesis of zero effects when in fact they are zero. Since they are probabilities, alpha values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This value may be interpreted as meaning that about one F-test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

You can specify different alpha values for different terms. For example, although you have three terms in an experiment, you might be mainly interested in only one of them. Hence, you could increase the alpha level of the tests of the other terms and thereby increase their power. Also, you may want to increase the alpha level of the interaction terms, as these will often have poor power otherwise.

**Beta**

These options specify the probability of a type-II error (beta) for each factor and interaction. A type-II error occurs when you fail to reject the null hypothesis of equal effects when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is becoming more common. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify a beta value of 0.10, you are specifying the corresponding power value of 0.90.
Sm (SD of Effects)
Enter the standard deviation of the effects ($\sigma_{effects}$) for this factor or interaction. This value represents the magnitude of the differences among the means (effects) that is to be detected.

The value of Sm may be entered in several ways: directly, as a list of numbers, or as a percentage of another term.

Directly
You can enter the value of Sm directly by specifying a single number. If only a single number is entered, it becomes the value of Sm.

You can use the Standard Deviation Estimator window to calculate the value of Sm for various sets of means. This window is obtained by selecting PASS, then Other, and then Standard Deviation Estimator from the menus.

List of Numbers
When a list of numbers is entered, the standard deviation of those numbers is computed and used as the value of Sm. The numbers in the list may represent means or effects. The list may be a simple list, the STEP command, or the RANGE command.

Simple List
A Simple List is a set of numbers separated by blanks or commas. Examples a simple list are

- 5 20 60
- 2,5,7
- -4,0,6,9

STEP Command
The syntax of the STEP command is $\text{STEP Start Inc}$. The list begins at $\text{Start}$ and increases by $\text{Inc}$. The number of values generated is determined by the number of levels in the term. Examples of the STEP command for a term with four levels are

- ‘STEP 0 2’ results in ‘0 2 4 6’.
- ‘STEP 1 -1’ results in ‘1 0 -1 -2’.
- ‘STEP 1 0.5’ results in ‘1 1.5 2 2.5’.

RANGE Command
The syntax of the RANGE command is $\text{RANGE Minimum Maximum}$. The list of numbers generated increase steadily from $\text{Minimum}$ to $\text{Maximum}$. The RANGE command is handy when you want to vary the number of levels while keeping the values in a known range. Examples of the RANGE command for a term with four levels are

- ‘RANGE 10 70’ results in ‘10 30 50 70’.
- ‘RANGE 0 1’ results in ‘0 0.33 0.67 1’.
- ‘RANGE 1 4’ results in ‘1 2 3 4’.
**Percentage of Another Term**

You can specify the value as a percentage of another term. The syntax of this command is `TERM PCT` where `TERM` is any other main effect or interaction in the model and `PCT` is a percentage. This method is often used to specify interaction Sm’s. Examples of the PERCENTAGE command are:

‘A 100’ results in an Sm equal to the Sm of factor A.

‘B 50’ results in an Sm equal to one-half of the Sm of factor B.

**Interactions**

The values of Alpha, Beta, and Sm are entered for various groups of interactions.

**Covariance Tab**

This tab specifies the covariance matrix.

**Specify Which Covariance Matrix Input Method to Use**

This option specifies which method will be used to define the covariance matrix.

**Standard Deviations and Correlations**

This option generates a covariance matrix based on the settings for the standard deviations (SD’s) and the pattern of autocorrelations as specified in the options on this screen down to and including ‘R2’. More about this option is given below.

**Covariance Matrix Variables**

When this option is selected, the covariance matrix is read in from the columns of the spreadsheet. This is the most flexible method, but specifying a covariance matrix is tedious. You will usually only use this method when a specific covariance is given to you. More about this option is given below.

Note that the spreadsheet is shown by selecting the menus: ‘Window’ and then ‘Data’.
1) Specify Covariance Matrix Using SD’s and Autocorrelations

The parameters in this section provide a flexible way to specify Σ, the covariance matrix. Because the covariance matrix is symmetric, it can be represented as

\[
Σ = \begin{bmatrix}
σ_{11} & σ_{12} & \cdots & σ_{1T} \\
σ_{12} & σ_{22} & \cdots & σ_{2T} \\
\vdots & \vdots & \ddots & \vdots \\
σ_{1T} & σ_{2T} & \cdots & σ_{TT}
\end{bmatrix}
\]

\[
= \begin{bmatrix}
σ_1 & σ_1σ_2ρ_{12} & \cdots & σ_1σ_Tρ_{1T} \\
σ_1σ_2ρ_{12} & σ_2 & \cdots & σ_2σ_Tρ_{2T} \\
\vdots & \vdots & \ddots & \vdots \\
σ_1σ_Tρ_{1T} & σ_2σ_Tρ_{2T} & \cdots & σ_T
\end{bmatrix}
\]

\[
= \begin{bmatrix}
σ_1 & 0 & \cdots & 0 \\
0 & σ_2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & σ_T
\end{bmatrix}
\begin{bmatrix}
1 & ρ_{12} & \cdots & ρ_{1T} \\
ρ_{12} & 1 & \cdots & ρ_{2T} \\
\vdots & \vdots & \ddots & \vdots \\
ρ_{1T} & ρ_{2T} & \cdots & 1
\end{bmatrix}
\begin{bmatrix}
σ_1 & 0 & \cdots & 0 \\
0 & σ_2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & σ_T
\end{bmatrix}
\]

where T is the product of the number of levels of all of the within factors.

Thus, the covariance matrix can be represented with complete generality by specifying the standard deviations \(σ_1, σ_2, \ldots, σ_T\) and the correlation matrix

\[
R = \begin{bmatrix}
1 & ρ_{12} & \cdots & ρ_{1T} \\
ρ_{12} & 1 & \cdots & ρ_{2T} \\
\vdots & \vdots & \ddots & \vdots \\
ρ_{1T} & ρ_{2T} & \cdots & 1
\end{bmatrix}
\]

Specify How the SD’s Change Across Time

This option specifies the method used to specify the standard deviations \(σ_1, σ_2, \ldots, σ_T\). Based on the method selected, the actual values are specified using SD1 and, in some cases, SD2.

Each \(σ\) is an estimate of the standard deviation that occurs when the same individual is measured at the same point in time under identical treatment conditions. It is a measure of the within-subject variability.

The available options are

**Constant (Use SD1. Ignore SD2)**

When this option is selected, the standard deviations are assumed to be equal. That is, it is assumed that \(σ_1 = \cdots = σ_T\). The value of \(σ_i\) is specified in the SD1 field. The value in the SD2 field is ignored.
**List of SD’s (Use list in SD1. Ignore SD2.)**
When this option is selected, a list of standard deviations can be entered in SD1. The items in the list can be separated by commas or blanks. The first value in the list becomes $\sigma_1$, the second value becomes $\sigma_2$, and so on. If the number of values in the list is less than the number of standard deviations required, the last value in the list is repeated. Note that all standard deviations in the list must be positive numbers.

**Range from SD1 to SD2 using the Time Metric**
When this option is selected, the standard deviations are spread between $\sigma_1$ and $\sigma_T$ according to the spread in the Time Metric. The value in SD1 becomes $\sigma_1$ and the value in SD2 becomes $\sigma_T$.

For example, suppose SD1 = 100, SD2 = 200, and the Time Metric values are 0, 2, 4, 10. The standard deviations would be
\[
\begin{align*}
\sigma_1 &= 100.0 \\
\sigma_2 &= 120.0 \\
\sigma_3 &= 140.0 \\
\sigma_4 &= 200.0
\end{align*}
\]

**Time Metric**
This option is used when the ‘How the SD’s Change Across Time’ option is set to ‘Range from SD1 to SD2 using the Time Metric’ to help define the covariance matrix. It specifies a sequential list of time points at which measurements of the subjects are made. Often, measurements are made at equally-spaced points through time. This is not always the case. It is important to define a time metric that corresponds to the study. For example, measurements might be planned at the beginning, after one day, after one week, and after one month.

The number of time points is the product of the number of levels of all within factors.

The time metric influences the values of the SD’s as well as the correlations between two measurements on the same individual.

**Entering a list of times**
A list of times can be entered in which the time values are separated by blanks or commas. The time metric can be defined in any time scale desired. For example, you could enter 0, 0.143, 1, 2, 3 if times were 0 weeks, 1/7 week (day 1), 1 week, 2 weeks, 3 weeks. The same values in days would be 0, 1, 7, 14, 21.
Using the RANGE command

The RANGE command can be used to specify a list of times. The syntax of the RANGE command is

RANGE Minimum Maximum

A set of equal-spaced time points is generated between Minimum and Maximum. The number of time points depends on the number of within-factor levels.

This setting is very useful when you want to study the impact of increasing/decreasing the number of measurements per subject during the same period of time. That is, if the study will last five weeks, will the power of the statistical tests increase if you take ten measurements rather than five?

For example, suppose there are six times. Entering

RANGE 0 10

will generate the time metric: 0, 2, 4, 6, 8, 10. If the number of times is changed to eleven, the time metric will become: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

Using the STEP command

The STEP command can be used to specify a list of times. The syntax of the STEP command is

STEP Start, Inc

This command generates time points beginning at Start and incrementing by Inc. For example,

STEP 0 2

would generate the values 0, 2, 4, 6, 8, …

SD1 (Standard Deviation 1)

This option is used to generate the covariance matrix. Its interpretation depends on the ‘How the SD’s Change Across Time’ option’s setting. Fundamentally, this is the standard deviation that occurs when the same individual is measured at the same point in time under identical treatment conditions. It is a measure of the within-subject variability.

You may want to use the special window that has been prepared to estimate SD1 from the mean square between (MSB) and the mean square within (MSW) of an existing table. To display this special window, from the menus select ‘PASS’, then ‘Other’, and then ‘Standard Deviation Estimator’. Click on the ‘Covariance Matrix’ tab. Enter the values from the ANOVA table. The resulting value of ‘Sigma’ should be placed here.

How the SD’s Change Across Time = Constant

The value entered here is used as the standard deviation for all time points.

How the SD’s Change Across Time = List of SD’s

The values in the list entered here become the values of the standard deviations. If the number in the list is less than the number required, the last value in the list is repeated.
How the SD’s Change Across Time = Range

The value entered here is used as a beginning standard deviation, the value in SD2 is used as an ending standard deviation, and the intermediate standard deviations are spaced between SD1 and SD2 proportional to the values of the Time Metric.

For example, suppose SD1 = 100, SD2 = 200, and the Time Metric values are 0,2,4,10. The standard deviation values would be:

S(1)=100
S(2)=120
S(3)=140
S(4)=200.

SD2 (Standard Deviation 2)

This parameter is used when ‘How the SD’s Change Across Time’ option is set to ‘Range…’. In that case, this option specifies the value of $\sigma_T$.

Specify How the Autocorr’s Change Across Time

This option specifies the pattern of the autocorrelations in the variance-covariance matrix. Three options are possible:

Constant

The value of R1 is used as the constant autocorrelation until the maximum time difference is reached, then the value of R2 is used. For example, if the maximum time difference is 3, R1 = 0.6, R2 = 0.1, and $T$ = 6, the correlation matrix would appear as

$$ R = \begin{bmatrix} 1 & 0.600 & 0.600 & 0.600 & 0.100 & 0.100 \\ 0.600 & 1 & 0.600 & 0.600 & 0.600 & 0.100 \\ 0.600 & 0.600 & 1 & 0.600 & 0.600 & 0.600 \\ 0.600 & 0.600 & 0.600 & 1 & 0.600 & 0.600 \\ 0.100 & 0.600 & 0.600 & 0.600 & 1 & 0.600 \\ 0.100 & 0.100 & 0.600 & 0.600 & 0.600 & 1 \end{bmatrix} $$

Note that when all correlations are equal, this is the correlation pattern that is assumed by the repeated measure ANOVA F-test. It may be a good first approximation, but many researchers believe the next option (first-order autocorrelation) is more realistic.
**1st Order Autocorrelation**

The value of R1 is used as the base autocorrelation in a first-order, serial correlation pattern. For example, if the maximum time difference is 3, R1 = 0.6, R2 = 0.1, and \( T = 6 \), the correlation matrix would appear as

\[
R = \begin{bmatrix}
1 & 0.600 & 0.360 & 0.216 & 0.100 & 0.100 \\
0.600 & 1 & 0.600 & 0.360 & 0.216 & 0.100 \\
0.360 & 0.600 & 1 & 0.600 & 0.360 & 0.216 \\
0.216 & 0.360 & 0.600 & 1 & 0.600 & 0.360 \\
0.100 & 0.216 & 0.360 & 0.600 & 1 & 0.600 \\
0.100 & 0.100 & 0.216 & 0.360 & 0.600 & 1 \\
\end{bmatrix}
\]

This pattern is often chosen as the most realistic when little is known about the correlation pattern.

**Custom**

The values of R1, R2, A, V, and Max Time Diff are used to generate a custom autocorrelation pattern. This relationship is modeled using the equation

\[
\text{Corr}(Y_{i1}, Y_{i2}) = \rho_{ij} = d \left( R1^{1-A+\lvert t_i-t_j \rvert} \right) + (1-d)R2
\]

where R1 is the base correlation, \( t_i \) and \( t_j \) are two time points, and A and V are specified constants. The variable \( d \) is one if \( \lvert t_i-t_j \rvert \) is less than Max Time Diff and zero otherwise.

Machin, Campbell, Fayers, and Pinol (1997) state that values of R1 between 0.60 and 0.75 are common.

We will present some examples to show you how this formula may be interpreted. For the moment, assume that the time metric is four, equally spaced time points of 1, 2, 3, and 4. Also, assume that Max Time Diff is set to 20.

**Example 1**

Let \( A = 0 \), \( V = 1 \), and \( \rho_{1} = \rho \). The correlation matrix becomes

\[
R = \begin{bmatrix}
1 & \rho & \rho & \rho \\
\rho & 1 & \rho & \rho \\
\rho & \rho & 1 & \rho \\
\rho & \rho & \rho & 1 \\
\end{bmatrix}
\]
Example 2
Let $A = 1$, $V = 1$, and $\rho_1 = \rho$. The correlation matrix becomes

$$R = \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$$

which is the first-order autoregression model, a popular model in time series analysis.

Example 3
Let $A = 1$, $V = 2$, and $\rho_1 = \rho$. The correlation matrix becomes

$$R = \begin{bmatrix} 1 & \rho^2 & \rho^4 & \rho^6 \\ \rho^2 & 1 & \rho^2 & \rho^4 \\ \rho^4 & \rho^2 & 1 & \rho^2 \\ \rho^6 & \rho^4 & \rho^2 & 1 \end{bmatrix}$$

which is similar to Example 2 except that the correlations die out much more quickly.

Example 4
Let $A = 0.5$, $V = 1$, and $\rho_1 = \rho$. The correlation matrix becomes

$$R = \begin{bmatrix} 1 & \rho^{0.5} & \rho^{1.0} & \rho^{1.5} \\ \rho^{0.5} & 1 & \rho^{0.5} & \rho^{1.0} \\ \rho^{1.0} & \rho^{0.5} & 1 & \rho^{0.5} \\ \rho^{1.5} & \rho^{1.0} & \rho^{0.5} & 1 \end{bmatrix}$$

which is similar to Example 2 except that the correlations die out much more slowly.

Example 5
Let $A = 1$ and $V = 1$. For this example, set the Max Time Diff option to 2. The correlation matrix becomes

$$R = \begin{bmatrix} 1 & \rho_1 & \rho_2 & \rho_2 \\ \rho_1 & 1 & \rho_1 & \rho_2 \\ \rho_2 & \rho_1 & 1 & \rho_1 \\ \rho_2 & \rho_2 & \rho_1 & 1 \end{bmatrix}$$

Notice that this scenario lets you create a banded correlation matrix with two unique correlations.
Example 6

This example shows how this formula works when the Max Time Diff is set to 7 and the time metric is 1, 2, 7, 15. Let $A = 1$ and $V = 1$. The correlation matrix becomes

$$R = \begin{bmatrix}
1 & \rho_1 & \rho_2 \\
\rho_1 & 1 & \rho_2 \\
\rho_2 & \rho_2 & 1
\end{bmatrix}$$

R1 (Autocorrelation)

This is the autocorrelation, $r_1$, between two measurements made on a subject at two time points that differ by one time unit. This value is combined with the other parameters in this section to form the covariance matrix.

Since this is a type of correlation, possible values range from -1 to 1. However, in this situation, a positive value is usually assumed, so the range is 0 to 1. A value near 0 indicates low autocorrelation. A value near 1 indicates high autocorrelation.

The value of this parameter depends on the Time Metric that is defined. Normally, you would expect a larger autocorrelation if the time metric units were in hours rather than days. In their book on sample size, Machin and Campbell comment the values between 0.60 and 0.75 are typical.

It is reasonable to assume that there is a correlation between two measurements made on the same subject at two points in time. It is often reasonable to assume that the size of this correlation diminishes as the two time points are further and further apart. That is, you would expect a much larger autocorrelation between two measurements taken one minute apart than between two measurements taken one week apart.

You may want to use the special window that has been prepared to estimate $R_1$ from the mean square between (MSB) and the mean square within (MSW) of an existing table. To display this special window, from the menus select ‘PASS’, then ‘Other’, and then ‘Standard Deviation Estimator’. Click on the ‘Covariance Matrix’ tab. Enter the values from the ANOVA table. The resulting value of ‘Rho should be placed here.

R2 (Second AC)

This is the value of the secondary autocorrelation, $R_2$. This value is used when the difference between two time points (see Time Metric) is greater than the value of Max Time Diff. Hence, if you set Max Time Diff to zero, this value will be used to calculate all correlations in the covariance matrix. When used, think of $R_2$ as the correlation between measurements made on the same subject, regardless of how far apart in time they are. Since we are assuming a positive autocorrelation, this value ranges between 0 and 1.

2) Specify Covariance Matrix using Spreadsheet Columns

This option instructs the program to read the covariance matrix from the spreadsheet.
Spreadsheet Columns Containing the Covariance Matrix
This option designates the columns on the current spreadsheet holding the covariance matrix. It is used when the ‘Specify Which Covariance Matrix Input Method to Use’ option is set to Covariance Matrix Variables.

The number of columns and number of rows must match the number of time periods at which the subjects are measured.

Reports Tab
This tab specifies which reports and graphs are displayed as well as their format.

Skip Line After
The names of the terms can be too long to fit in the space provided. If the name contains more characters than this, the rest of the output is placed on a separate line. Enter ‘1’ when you want every term’s results printed on two lines. Enter ‘100’ when you want every variable’s results printed on one line.

Test in Summary Statement
Indicate the test that is to be reported on in the Summary Statements.

Maximum Term-Order Reported
Indicate the maximum order of terms to be reported on. Occasionally, higher-order interactions are of little interest and so they may be omitted. For example, enter a ‘2’ to limit output to individual factors and two-way interactions.
Example 1 - Determining Sample Size

Researchers are planning a study of the impact of a drug on heart rate. They want to evaluate the differences in heart rate among three age groups: 20-40, 41-60, and over 60. Their experimental protocol calls for a baseline heart rate measurement, followed by administration of a certain level of the drug, followed by three additional measurements 30 minutes apart. They want to be able to detect a 10% difference in heart rate among the age groups. They want to detect 5% difference in heart rate within an individual across time. They decide the experiment should detect interaction effects of the same magnitude as the time factor. They plan to analyze the data using a Geisser-Greenhouse corrected F test.

Similar studies have found an average heart rate of 93, a standard deviation of 4, and an autocorrelation between adjacent measurements on the same individual of 0.7. The researchers assume that first-order autocorrelation adequately represents the autocorrelation pattern.

From a heart rate of 93, a 10% reduction gives 84. They decide on the age-group means of 93, 87, and 84. Similarly, a 5% reduction within a subject would result in a heart rate of 88. They decide on time means of 93, 89, 88, and 91.

How many subjects per age group are needed to achieve 95% power and a 0.05 significance level?

Setup

Annotated Output
Click the Run button to perform the calculations and generate the following output.
The Design Report gives the power for each term in the design for each value of \( n \). It is useful when you want to compare the powers of the terms in the design at a specific sample size.

In this example, the design goals of 0.95 power on all terms are achieved for \( n = 6 \).

The definitions of each of the columns of the report are as follows.

**Term**  
This column contains the identifying label of the term. The number of levels for a factor is given in parentheses.

**Test**  
This column identifies the test statistic. Since the power depends on the test statistic, you should make sure that this is the test statistic that you will use.

**Power**  
This is the computed power for the term.

\( n \)  
The value of \( n \) is the number of subjects per group.

\( N \)  
The value of \( N \) is the total number of subjects in the study.
### Multiply Means By
This is the value of the means multiplier, $K$.

### SD of Effects (Sm)
This is the standard deviation of the effects $\sigma_m$ for this term.

### Standard Deviation
This is the value of $\sigma$, the random variation that $\sigma_m$ is compared against by the $F$ test. See the Technical Details for details on how these values are calculated.

### Effect Size
The Effect Size is calculated by the expression $\sigma_m / \sigma$. It is an index of the size of the effect values relative to the standard deviation. Its value may be compared from experiment to experiment, regardless of the scale of the response variable.

### Alpha
Alpha is the significance level of the test

### Beta
Beta is the probability of failing to reject the null hypothesis when the alternative hypothesis is true.

</table>

This report gives the details of the components of the Geisser-Greenhouse correction for each term and sample size. It is useful when you want to compare various aspects of this test.

The definitions of each of the columns of the report are as follows.

**Term**
This column contains the identifying label of the term. For factors, the number of levels is also given in parentheses.

**Power**
This is the computed power for the term.
Alpha
Alpha is the significance level of the test.

Critical F
This is the critical value of the F statistic. An F value computed from the data that is larger than this value is statistically significant at the alpha level given.

Lambda
This is the value of the noncentrality parameter $\lambda$ of the approximate noncentral $F$ distribution.

df1|df2
These are the values of the numerator and denominator degrees of freedom of the approximate $F$ test that is used. These values are useful when comparing various designs. Other things being equal, you would like to have df2 large and df1 small.

Epsilon
The Geisser-Greenhouse epsilon is a measure of how far the covariance matrix departs from the assumption of circularity.

E(Epsilon)
This is the expected value of epsilon. It is a measure of how far the covariance matrix departs from the assumption of circularity.

G1
$G1$ is part of a correction factor used to convert $\varepsilon$ to $E(\hat{\varepsilon})$. It is reported for your convenience.

Summary Statements
A repeated measures design with 1 between factor and 1 within factor has 3 groups with 2 subjects each for a total of 6 subjects. Each subject is measured 4 times. This design achieves 31% power to test factor B if a Geisser-Greenhouse Corrected F Test is used with a 5% significance level and the actual effect standard deviation is 3.74 (an effect size of 1.14), achieves 33% power to test factor W if a Geisser-Greenhouse Corrected F Test is used with a 5% significance level and the actual effect standard deviation is 1.92 (an effect size of 1.47), and achieves 16% power to test the BW interaction if a Geisser-Greenhouse Corrected F Test is used with a 5% significance level and the actual effect standard deviation is 1.92 (an effect size of 1.47).

A summary statement can be generated for each sample size that is used. This statement gives the results in sentence form. The number of designs reported on textually is controlled by the Summary Statement option on the Report tab.
Means Matrix

<table>
<thead>

<td>4.58</td>
<td>0.00</td>
</tr>
</tbody>
</table>

This report shows the means matrix that was read in from the spreadsheet or generated by the Sm values that were given. It may be used to get an impression of the magnitude of the difference among the means that is being studied. When a Means Multiplier, $K$, is used, each value of $K$ is multiplied times each value of this matrix.

Variance-Covariance Matrix Section

<table>

</tr>
<tr>
<td>W4</td>
</tr>
</tbody>
</table>

This report shows the variance-covariance matrix that was read in from the spreadsheet or generated by the settings of on the Covariance tab. The standard deviations are given on the diagonal and the autocorrelations are given off the diagonal.

Chart Section

The chart shows the relationship between power and $n$ for the terms in the design. Note that high-order interactions may be omitted from the plot by reducing the Max Term-Order Plotted option on the Plot Setup tab.
Example 2 - Varying the Difference Between the Means

Continuing with Example 1, the researchers want to evaluate the impact on power of varying the size of the difference among the means for a range of sample sizes from 2 to 8 per groups. The researchers could try calculating various multiples of the means, inputting them, and recording the results. This can be accomplished very easily by using the $K$ option.

Keeping all other settings as in Example 1, the value of $K$ is varied from 0.2 to 3.0 in steps of 0.2. We determined these values by experimentation so that a full range of power values are shown on the plots.

In the output to follow, we only display the plots. You may want to display the numeric reports as well, but we do not here in order to save space.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

Annotated Output
Click the Run button to perform the calculations and generate the following output.

These charts show how the power depends on the relative size of $Sm$ (i.e. $K$) as well as the group sample size $n$. 
Example 3 - Impact of the Number of Repeated Measurements

Continuing with Example 1, the researchers want to study the impact on power of changing the number of measurements made on each individual. Their experimental protocol calls for four measurements that are 30 minutes apart. They want to see the impact of taking twice that many measurements. To keep the output simple and two the point, they decide to look at the case when \( n = 4 \) and \( K = 1 \).

Setup

You can enter these values yourself or load the Example3 template from the Template tab.

</table>

Notice that the power of the between subjects factor decreased slightly, the power of the within-subjects factor increased slightly, and the power of the interaction test decreased slightly. This pattern of increase or decrease depends on all the settings.

We tried varying the value of the autocorrelation from 0.7 to 0.1 and found this to impact the direction of the change in the number of measurements. Hence, our conclusion is that there is no single answer. Changing the number of measurements may increase or decrease the power of a specific test depending on the values of the other parameters.
Example 4 - Power after a study

This example will show how to calculate the power of $F$ tests from data that have already been collected and analyzed using the analysis of variance. The following results were obtained using the analysis of variance procedure in NCSS. In this example, Gender is the between factor with two levels and Treatment is the within factor with three levels. The experiment was conducted with two subjects per group, but there is interest in the power for 2, 3, and 4 subjects per group. All significance levels are set to 0.05.

</tbody>
</table>

Note that the treatment means (L, M, and H) show an increasing pattern from 16.75 to 18.25, but the hypothesis test of this factor is not statistically significant at the 0.05 level. We will now calculate the power of the three $F$ tests using PASS. We will use the regular $F$ test since that is what was used in the above table.

From the above printout, we note that $MSB = 0.6666667$ and $MSW = 0.4166667$. Plugging these values into the estimating equations

$$
\hat{\rho} = \frac{MSB - MSW}{MSB + (T - 1)MSW}
$$

$$
\hat{\sigma}^2 = \frac{MSW}{1 - \hat{\rho}}
$$

yields

$$
\hat{\rho} = \frac{0.6666667 - 0.4166667}{0.6666667 + (3 - 1)0.4166667} = 0.1666667
$$

$$
\hat{\sigma}^2 = \frac{0.4166667}{1 - 0.1666667} = 0.5
$$
so that

$$\hat{\sigma} = \sqrt{0.5} = 0.70710681$$

With these values calculated, we can setup PASS to calculate the power of the three \( F \) tests as follows.

**Setup**

<td>0.0199</td>
</tr>
</tbody>
</table>

You can see that the power of the tests on W and BW was only 0.55 for an n of 2. However, if n would have been 3, a much more reasonable power of 0.89 would have been achieved.
Example5 - Cross-over Design

A crossover design is a special type of repeated measures design in which the treatments are applied to the subjects in different orders. The between-subjects (grouping) factor is defined by the specific sequence in which the treatments are applied. For example, suppose the treatments are represented by B1 and B2. Further suppose that half the subjects receive treatment B1 followed by treatment B2 (sequence B1B2), while the other half receive treatment B2 followed by treatment B1 (sequence B2B1). This is a two-group crossover design.

Crossover designs assume that a long enough period elapses between measurements so that the effects of one treatment are washed out before the next treatment is applied. This is known as the assumption of no carryover effects.

When a crossover design is analyzed using repeated measures, the interaction is the only term of interest. The $F$ test on the between factor tests whether averages across each sequence are equal—a test of little interest. The $F$ test on the within factor tests whether the response is different across the time periods—also of little interest. The $F$ test for interaction tests whether the change in response across time is the same for both sequences. The interaction can only be significant if the treatments effect the outcome differently. Hence, to specify a crossover design requires the careful specification of the interaction effects.

With this background, we present an example. Suppose researchers want to investigate the reduction in heart-beat rate caused by the administration of a certain drug using a simple two-period crossover design. The researchers want a sample size large enough to detect a drop in heart-beat rate from 95 to 90 with a power of 90% at the 0.05 significance level. Previous studies have shown a within-patient autocorrelation of 0.50 and a standard deviation of 3.98. They decide to consider sample sizes between 2 and 8.

The hypothesized interaction is specified by entering the mean heart-beat rates of the four treatment groups as 95, 90, 90, and 95. Since the standard deviation of these values is all that is used, the order of these values does not matter. In this case the sequences means are both 92.5 and the average time-period means are both 92.5. Hence, the interaction effects are 2.5, -2.5, -2.5, and 2.5. You can check that the set of numbers ‘95, 90, 90, 95’ has the same standard deviation as the set ‘2.5, -2.5, -2.5, 2.5’ or even ‘5, 0, 0, 5’. All of these will work.

Setup

You can enter these values yourself or load the Example5 template from the Template tab.

We only display the interaction term since that is the only term of interest. A quick glance at the plot shows that 90% power is achieved when \( n \) is five. This corresponds to a total sample size of ten subjects.
Example 6 - Power of a Completed Crossover Design

The following analysis of variance table was generated by NCSS for a set of crossover data. Find the power of the interaction $F$ test assuming a significance level of 0.05.

</tbody>
</table>

One difficulty in analyzing an existing crossover design is determining an appropriate value for the hypothesized interaction effects. One method is to find the standard deviation of the interaction effects by taking the square root of the Sum of Squares for the interaction divided by the total number of observations. In this case,

$$\sigma_{Interaction} = \sqrt{\frac{122401.7}{60}} = 45.1667$$

Another method is to find the individual interaction effects by subtraction. This method proceeds as follows.

First, subtract the Period means from the Sequence by Period means.

$$\begin{bmatrix} 364.2000 & 531.7333 \\ 543.0000 & 529.8666 \end{bmatrix} - \begin{bmatrix} 447.9667 \\ 536.4333 \end{bmatrix} = \begin{bmatrix} -83.7667 & 83.7667 \\ 6.5667 & -6.5667 \end{bmatrix}$$

Next, compute the column means and subtract them from the current values. This results in the effects.

$$\begin{bmatrix} -83.7667 & 83.7667 \\ 6.5667 & -6.5667 \end{bmatrix} - \begin{bmatrix} -38.6000 & 38.6000 \\ -38.6000 & 38.6000 \end{bmatrix} = \begin{bmatrix} -45.1667 & 45.1667 \\ 45.1667 & -45.1667 \end{bmatrix}$$

Finally, compute the standard deviation of the effects. Since the mean of the effects is zero, the standard deviation is
\[
\sigma_{\text{Interaction}} = \sqrt{\frac{(-45.1667)^2 + (45.1667)^2 + (45.1667)^2 + (-45.1667)^2}{4}} \\
= 45.1667
\]

Another difficulty that must be solved is to estimate the autocorrelation and within-subject standard deviation. From the above printout, we note that MSB = 75383.54 and MSW = 83919.72. Plugging these values into the estimating equations

\[
\hat{\rho} = \frac{MSB - MSW}{MSB + (T - 1)MSW} \\
\hat{\sigma}^2 = \frac{MSW}{1 - \hat{\rho}}
\]

yields

\[
\hat{\rho} = \frac{75383.54 - 83919.72}{75383.54 + (2 - 1)83919.72} = -0.05358447 \\
\hat{\sigma}^2 = \frac{83919.72}{1 + 0.05358447} = 79651.63
\]

so that

\[
\hat{\sigma} = \sqrt{79651.63} = 282.2262
\]

**Setup**

You can enter these values yourself or load the Example6 template from the Template tab.

</table>

Notice that these power values are low. Fifteen was not a large enough sample size to detect Sm values near 40.
Example 7 - Validation using O’Brien and Muller

O’Brien and Muller’s article in the book edited by Edwards (1993) analyze the power of a two-group repeated-measures experiment in which three measurements are made on each subject.

The hypothesized means are

<table>
<thead>
<tr>
<th></th>
<th>Group 1</th>
<th>Group 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time 1</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>Time 2</td>
<td>12</td>
<td>5</td>
</tr>
<tr>
<td>Time 3</td>
<td>8</td>
<td>7</td>
</tr>
</tbody>
</table>

The covariance matrix is

<table>
<thead>
<tr>
<th></th>
<th>Time 1</th>
<th>Time 2</th>
<th>Time 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time 1</td>
<td>25</td>
<td>16</td>
<td>12</td>
</tr>
<tr>
<td>Time 2</td>
<td>16</td>
<td>64</td>
<td>30</td>
</tr>
<tr>
<td>Time 3</td>
<td>12</td>
<td>30</td>
<td>36</td>
</tr>
</tbody>
</table>

With \( n \)'s of 12, 18, and 24 and an alpha of 0.05, they obtained power values using the Wilks’ Lambda test. Their reported power values are

<table>
<thead>
<tr>
<th>( n )</th>
<th>Group</th>
<th>Time</th>
<th>Interaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>0.326</td>
<td>0.983</td>
<td>0.461</td>
</tr>
<tr>
<td>18</td>
<td>0.467</td>
<td>0.999</td>
<td>0.671</td>
</tr>
<tr>
<td>24</td>
<td>0.589</td>
<td>0.999</td>
<td>0.814</td>
</tr>
</tbody>
</table>

O’Brien, in a private communication, re-ran these data using the Geisser-Greenhouse correction. His results were as follows:

<table>
<thead>
<tr>
<th>( n )</th>
<th>Group</th>
<th>Time</th>
<th>Interaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>0.326</td>
<td>0.993</td>
<td>0.486</td>
</tr>
<tr>
<td>18</td>
<td>0.467</td>
<td>0.999</td>
<td>0.685</td>
</tr>
<tr>
<td>24</td>
<td>0.589</td>
<td>0.999</td>
<td>0.819</td>
</tr>
</tbody>
</table>

In order to run this example in PASS, the values of the means and the covariance matrix (given above) must be entered on a spreadsheet. We have loaded these values into the database called OBRIEN. Either enter the values yourself, or load the OBRIEN database which should be in the Data directory. The instructions below assume that the means are in columns one and two, while the covariance matrix is in columns four through six of the current database.

Setup

You can enter these values yourself or load the Example7 template from the Template tab.

PASS agrees exactly with O’Brien’s calculations.

## Example 8 - Unequal Group Sizes

Usually, in the planning stages, the group sample sizes are equal. Occasionally, however, you may want to plan for a situation in which one group will have a much larger sample size than the others. Also, when doing a power analysis on a study that has already been conducted, the group sample sizes are often unequal.

In this example, we will re-analyze the Example 4. However, we will now assume that there were four subjects in group 1 and eight subjects in group 2. The setup and output for this example are as follows. Remember that you must open the database PASS RM EXAMPLE2 before running this example.

### Setup

You can enter these values yourself or load the Example8 template from the Template tab.

Notice that the values of n are now shown to one decimal place. That is because the value reported is the average value of n. The actual n’s are shown following the report.
Example 9 - Designs with More Than Two Factors

Occasionally, you will have a design that has more than two factors. We will now show you how to compute the necessary sample size for such a design.

Suppose your design calls for two between-subject factors, Age (A) and Gender (G), and two within-subject factors, Dose-Level (D) and Application-Method (M). Suppose the number of levels of these four factors are, respectively, 3, 2, 4, and 2.

Our first task is to determine appropriate values of Sm for each of the terms. We decide to ignore the interactions during the planning and only consider the factors themselves. The desired difference to be detected among the three age groups can be represented by the means 80, 88, and 96. The desired difference to be detected among the two genders can be represented by the means 80 and 96. The desired difference to be detected among the four dose levels is represented by the means 80, 82, 84, and 86. The desired difference to be detected among the two application methods is represented by the means 80 and 86.

Our next task is to specify the covariance matrix. From previous experience, we have found that a constant value of 20.0 is appropriate for SD1. An autocorrelation of 0.5 with a first-order autocorrelation pattern is also appropriate.

Finally, we decide to calculate the power using the GG F test at the following sample sizes: 2, 4, 6, 8, 10, 20, 30, and 40.

Setup

Annotated Output
Click the Run button to perform the calculations and generate the following output.
This report gives the power values for the various terms and sample sizes that were entered. It is much easier to consider the following plot to interpret the results.
From this chart, we can see that the first within-subject factor, dose level, has a power much lower than the other factors. Looking at the Sm values in the numeric table, we find that the Sm value for factor D is much less than for the other values. This explains why its power is so poor. Our options are to either increase the sample size or increase the value of Sm for factor D.
Chapter 575

Multiple Comparisons

Introduction

This module computes sample sizes for multiple comparison procedures. The term “multiple comparison” refers to the individual comparison of two means selected from a larger set of means. The module emphasizes one-way analysis of variance designs that use one of three multiple-comparison methods: Tukey’s all pairs (MCA), comparisons with the best (MCB), or Dunnett’s all versus a control (MCC). Because these sample sizes may be substantially different from those required for the usual $F$ test, a separate module is provided to compute them.

There are only a few articles in the statistical literature on the computation of sample sizes for multiple comparison designs. This module is based almost entirely on the book by Hsu (1996). We can give only a brief outline of the subject here. Users who want more details are referred to Hsu’s book.

Although this module is capable of computing sample sizes for unbalanced designs, it emphasizes balanced designs.

Technical Details

The One-Way Analysis of Variance Design

The summarized discussion that follows is based on the common, one-way analysis of variance design. Suppose the responses $Y_{ij}$ in $k$ groups each follow a normal distribution with respective means, $\mu_1, \mu_2, \cdots, \mu_k$, and unknown variance, $\sigma^2$. Let $n_1, n_2, \cdots, n_k$ denote the number of subjects in each group.

The analysis of these responses is based on the sample means

$$\hat{\mu}_i = \bar{Y}_i = \sum_{j=1}^{n_i} \frac{Y_{ij}}{n_i}$$

and the pooled sample variance

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2}{\sum_{i=1}^{k} (n_i - 1)}$$
The $F$ test is the usual method for analyzing such a design, and tests whether all of the means are equal. However, a significant $F$ test does not indicate which of the groups are different, only that at least one is different. The analyst is left with the problem of determining which group(s) is(are) different and by how much.

The probability statement associated with the $F$ test is simple, straightforward, and easy to interpret. However, when several simultaneous comparisons are made among the group means, the interpretation of individual probability statements becomes much more complex. This is called the problem of multiplicity. Multiplicity here refers to the fact that the probability of making at least one incorrect decision increases as the number of statistical tests increases. The method of multiple comparisons has been developed to account for such multiplicity.

**Power Calculations for Multiple Comparisons**

For technical reasons, the definition of power in the case of multiple comparisons is different from the usual definition. Following Hsu (1996) page 237, power is defined as follows.

Using a $1 - \alpha$ simultaneous confidence interval multiple comparison method, power is the probability that the confidence intervals cover the true parameter values and are sufficiently narrow. Power is still defined to be $1 - \beta$. Note that $1 - \beta < 1 - \alpha$. Here, narrow refers to the width of the confidence intervals. The definition says that the confidence intervals should be as narrow as possible while still including the true parameter values. This definition may be restated as the probability that the simultaneous confidence intervals are correct and useful.

The parameter $\omega$ represents the maximum width of any of the individual confidence intervals in the set of simultaneous confidence intervals. Thus, $\omega$ is used to specify the narrowness of the confidence intervals.

**Multiple Comparisons with a Control (MCC)**

A common experimental design compares one or more treatment groups with a control group. The control group may receive a placebo, the standard treatment, or even an experimental treatment. The distinguishing feature is that the mean response of each of the other groups is to be compared with this control group.

We arbitrarily assume that the last group (group $k$), is the control group. The $k-1$ parameters of primary interest are

\[
\delta_1 = \mu_1 - \mu_k \\
\delta_2 = \mu_2 - \mu_k \\
\vdots \\
\delta_i = \mu_i - \mu_k \\
\vdots \\
\delta_{k-1} = \mu_{k-1} - \mu_k
\]

In this situation, Dunnett’s method provides simultaneous, one- or two-sided confidence intervals for all of these parameters.

The one-sided confidence intervals, $\delta_1, \cdots, \delta_{k-1}$, are specified as follows:

\[
\Pr\left(\delta_i > \hat{\mu}_i - \hat{\mu}_k - q_{\alpha, df, \lambda_i, \cdots, \lambda_{k-1}} \hat{\sigma} \sqrt{\frac{1}{n_i} + \frac{1}{n_k}} \right) = 1 - \alpha
\]
where
\[ \lambda_i = \sqrt{\frac{n_i}{n_i + n_k}} \]
and \( q \), found by numerical integration, is the solution to
\[ \int \int \prod_{i=1}^{k-1} \left[ \Phi \left( \frac{\lambda_i z + qs}{\sqrt{1 - \lambda^2}} \right) \right] d\Phi(z) \gamma(s) ds = 1 - \alpha \]
where \( \Phi(z) \) is the standard normal distribution function and \( \gamma(z) \) is the density of \( \hat{\sigma} / \sigma \).

The two-sided confidence intervals for \( \delta_1, \ldots, \delta_{k-1} \) are specified as follows:
\[ \Pr \left( \delta_i \in \hat{\mu}_i - \hat{\mu}_k - |q|, \text{df}, \lambda_1, \ldots, \lambda_{k-1} \right) = 1 - \alpha \]
where
\[ \lambda_i = \sqrt{\frac{n_i}{n_i + n_k}} \]
and \( |q| \), found by numerical integration, is the solution to
\[ \int \int \prod_{i=1}^{k-1} \left[ \Phi \left( \frac{\lambda_i z + |q|s}{\sqrt{1 - \lambda^2}} \right) - \Phi \left( \frac{\lambda_i z - |q|s}{\sqrt{1 - \lambda^2}} \right) \right] d\Phi(z) \gamma(s) ds = 1 - \alpha \]
where \( \Phi(z) \) is the standard normal distribution function and \( \gamma(z) \) is the density of \( \hat{\sigma} / \sigma \).

**Interpretation of Dunnett’s Simultaneous Confidence Intervals**

There is a specific interpretation given for Dunnett’s method. It provides a set of confidence intervals calculated so that, if the normality and equal-variance assumptions are valid, the probability that all of the \( k-1 \) confidence intervals enclose the true values of \( \delta_1, \ldots, \delta_{k-1} \) is \( 1 - \alpha \).

The presentation below is for the two-sided case. The one-sided case is the same as for the MCB case.

**Sample Size and Power - Balanced Case**

Using the modified definition of power, the two-sided case is outlined as follows.
\[ \Pr \left( \text{simultaneous coverage and narrow} \right) = \Pr \left( \mu_i - \mu_j \in \hat{\mu}_i - \hat{\mu}_j \pm |q|\hat{\sigma} \sqrt{2/n} \text{ for } i = 1, \ldots, k-1 \right) \text{ and } \left( |q|\hat{\sigma} \sqrt{2/n} < \omega / 2 \right) \]
\[ = k \int_{-\infty}^{\infty} \left[ \Phi \left( z + \sqrt{2}|q|s \right) - \Phi \left( z - \sqrt{2}|q|s \right) \right]^{k-1} d\Phi(z) \gamma(s) ds \]
\[ \geq 1 - \beta \]
where
$$u = \frac{\omega / 2}{\sigma q\sqrt{\frac{2}{n}}}$$

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of \( \omega = \mu_i - \mu_j \) that you want to detect, the group sample size, \( n \), the power, \( 1 - \beta \), the significance level, \( \alpha \), and the within-group standard deviation, \( \sigma \).

### Sample Size and Power - Unbalanced Case

Using the modified definition of power, the unbalanced case is outlined as follows.

\[
\Pr\left( \text{simultaneous coverage and (narrow)} \right) = \Pr\left( \left( \mu_i - \mu_k \in \hat{\mu}_i - \hat{\mu}_k \pm q|\hat{\sigma}| \sqrt{\frac{1}{n_i} + \frac{1}{n_k}} \text{ for } i = 1, \ldots, k - 1 \right) \text{ and } \left( \min_{i < k} \left[ q|\hat{\sigma}| \sqrt{\frac{1}{n_i} + \frac{1}{n_k}} \right] < \omega / 2 \right) \right) \\
= k \int_{0}^{\infty} \int_{0}^{\infty} \Phi(z) - \Phi(z - \sqrt{2}|q|s) \right)^{k-1} d\Phi(z)\varphi(s)ds \\
\geq 1 - \beta
\]

where

\[
u = \frac{\omega / 2}{\min_{i < k} \left[ q|\hat{\sigma}| \sqrt{\frac{1}{n_i} + \frac{1}{n_k}} \right]}
\]

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of \( \omega = \mu_i - \mu_j \) that you want to detect, the group sample sizes, \( n_1, n_2, \ldots, n_k \), the power, \( 1 - \beta \), the significance level, \( \alpha \), and the within-group standard deviation, \( \sigma \).

### Multiple Comparisons with the Best (MCB)

The method of multiple comparisons with the best (champion) is used in situations in which the best group (we will assume the best is the largest, but it could just as well be the smallest) is desired. Because of sampling variation, the group with the largest sample mean may not actually be the group with the largest population mean. The following methodology has been developed to analyze data in this situation.

Perhaps the most obvious way to define the parameters in this situation is as follows

\[
\max_{j=1, \ldots, k} \mu_j - \mu_i, \text{ for } i = 1, \ldots, k
\]

Obviously, the group for which all of these values are positive will correspond to the group with the largest mean.

Another way of looking at this, which has some advantages, is to use the parameters

\[
\theta_i = \mu_i - \max_{i \neq j} \mu_j, \text{ for } i = 1, \ldots, k
\]
since, if $\theta_i > 0$, group $i$ is the best.

Hsu (1996) recommends using constrained MCB inference in which the intervals are constrained to include zero. Hsu recommends this because inferences about which group is best are sharper. For example, a confidence interval for $\theta_i$ whose lower limit is 0 indicates that group $i$ is the best. Similarly, a confidence interval for $\theta_i$ whose upper limit is 0 indicates that group $i$ is not the best.

Hsu (1996) shows that $100(1 - \alpha)_\alpha$ simultaneous confidence intervals for $\theta_i$ are given by

\[
- \min \left[ 0, \left( \hat{\theta}_i - q_\alpha,df_i,\ldots,\hat{\theta}_k,\ldots,\hat{\theta}_k \right) \right] \leq \max \left[ 0, \left( \hat{\theta}_i + q_\alpha,df_i,\ldots,\hat{\theta}_k,\ldots,\hat{\theta}_k \right) \right], \quad i = 1, \ldots, k
\]

where $q^i$ is found using Dunnett’s one-sided procedure discussed above assuming that group $i$ is the control group.

**Sample Size and Power - Balanced Case**

Using the modified definition of power, the balanced case is outlined as follows

\[
\Pr\left[ \text{(simultaneous coverage) and (narrow)} \right] = k \int_0^\infty \int_{-\infty}^{\infty} \Phi(z + \sqrt{2}qs)^{k-1} d\Phi(z)\gamma(s) ds \geq 1 - \beta
\]

where

\[
u = \frac{\omega / 2}{\sigma q \sqrt{2 / n}}
\]

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of $\omega = \mu_i - \mu_j$ that you want to detect, the group sample size, $n$, the power, $1 - \beta$, the significance level, $\alpha$, and the within-group standard deviation, $\sigma$.
Sample Size and Power - Unbalanced Case

Using the modified definition of power, the unbalanced case is outlined as follows

$$
\text{Pr}\left[\text{Simultaneous coverage and narrow}\right]
= \text{Pr}\left[\begin{array}{l}
\min_{i \neq j} \left( \hat{\mu}_i - \max_{j \neq i} \hat{\mu}_j - q' \hat{\sigma} \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} \right) \\
\max_{i \neq j} \left( \hat{\mu}_i - \max_{j \neq i} \hat{\mu}_j + q' \hat{\sigma} \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} \right) \text{ for } i = 1, \ldots, k \\
\text{and} \quad \min_{i \neq j} \left[ q' \hat{\sigma} \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} < \frac{\omega}{2} \right] 
\end{array}\right] 
= k \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \Phi\left(z + \sqrt{2}q|s|\right)^{k-1} \Phi\left(z\right) \gamma(s) ds
\geq 1 - \beta
$$

where

$$
u = \max_{i \neq j} \left( \frac{\omega / 2}{\sigma^{j} \sqrt{\frac{1}{n_i} + \frac{1}{n_j}}} \right)
$$

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of $\omega = \mu_i - \mu_j$ that you want to detect, the group sample sizes, $n_1, n_2, \ldots, n_k$, the power, $1 - \beta$, the significance level, $\alpha$, and the within-group standard deviation, $\sigma$. 
All-Pairwise Comparisons (MCA)
In this case you are interested in all possible pairwise comparisons of the group means. There are \( k(k-1)/2 \) such comparisons. A popular method in this case is that developed by Tukey.

Balanced Case
The Tukey method provides simultaneous, two-sided confidence intervals. They are specified as follows

\[
Pr\left( \mu_i - \mu_j \in \hat{\mu}_i - \hat{\mu}_j \pm q^*|\bar{\sigma}\sqrt{\frac{2}{n}} \text{ for } i \neq j \right) = 1 - \alpha
\]

When all the sample sizes are equal, \( q^* \) may be found by numerical integration as the solution to the equation

\[
\int \int \prod_{i=1}^{k-1} \left[ \Phi(z) - \Phi\left(z - \sqrt{2}q^*\frac{|\bar{\sigma}|}{\sigma}\right) \right] d\Phi(z) \gamma(s) ds = 1 - \alpha
\]

where \( \Phi(z) \) is the standard normal distribution function and \( \gamma(z) \) is the density of \( \bar{\sigma} / \sigma \). Note that \( q^* = \sqrt{2}|q^*| \) is the critical value of the Studentized range distribution.

Sample Size and Power
Using the modified definition of power, the balanced case is outlined as follows

\[
Pr\left[ (\text{simultaneous coverage}) \text{ and } (\text{narrow}) \right]
\]

\[
= Pr\left[ (\mu_i - \mu_j \in \hat{\mu}_i - \hat{\mu}_j \pm q^*|\bar{\sigma}\sqrt{2/n} \text{ for all } i \neq j) \text{ and } (|q^*|\bar{\sigma}\sqrt{2/n} < \bar{\sigma}/\sigma) \right]
\]

\[
= k \int \int \prod_{i=1}^{k-1} \left[ \Phi(z) - \Phi\left(z - \sqrt{2}q^*|s|\right) \right] d\Phi(z) \gamma(s) ds
\]

\[
\geq 1 - \beta
\]

where

\[
u = \frac{\sigma/\bar{\sigma}\sqrt{2/n}}{q^*|s|}
\]

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of \( \omega = \mu_i - \mu_j \) that you want to detect, the group sample size, \( n \), the power, \( 1 - \beta \), the significance level, \( \alpha \), and the within-group standard deviation, \( \sigma \).
Unbalanced Case
The simultaneous, two-sided confidence intervals are specified as follows

\[
\Pr \left( \mu_i - \mu_j \in \hat{\mu}_i - \hat{\mu}_j \pm q^* \sigma \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} \text{ for } i \neq j \right) = 1 - \alpha
\]

Unfortunately, \( q^* \) cannot be calculated as a double integral as in previous cases. Instead, the Tukey-Kramer approximate solution is used. Their proposal is to use \( q^* \) in place of \( q^e \).

Sample Size and Power
Using the modified definition of power, the unbalanced case is outlined as follows

\[
\Pr \left( \text{simultaneous coverage and narrow} \right)
\]

\[
= \Pr \left( \left( \mu_i - \mu_j \in \hat{\mu}_i - \hat{\mu}_j \pm q^* \sigma \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} \text{ for all } i \neq j \right) \text{ and } \left( \min_{i \neq j} \left[ q^* \sigma \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} < \omega / 2 \right] \right) \right)
\]

\[
= k \int_{-\infty}^{+\infty} \int_0^{+\infty} \Phi(z) - \Phi(z - \sqrt{2}q^* s) \left[ 1 - \Phi(z) \right] d\Phi(z) \gamma(s) ds
\]

\[\geq 1 - \beta\]

where

\[
u = \frac{\omega / 2}{\min_{i \neq j} \left[ q^* \sigma \sqrt{\frac{1}{n_i} + \frac{1}{n_j}} \right]}
\]

This calculation is made using the algorithm developed by Hsu (1996).

To reiterate, this calculation requires you to specify the minimum value of \( \omega = \mu_i - \mu_j \) that you want to detect, the group sample sizes, \( n_1, n_2, \ldots, n_k \), the power, \( 1 - \beta \), the significance level, \( \alpha \), and the within-group standard deviation, \( \sigma \).
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, refer to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for using the other parameters. Under most situations you will select either Beta for a power analysis or \( n \) for sample size determination.

\( k \) (Number of Groups)

This is the number of group means being compared. It must be greater than or equal to three.

You can enter a list of values, in which case a separate analysis will be calculated for each value. Commas or blanks may separate the numbers. A TO-BY list may also be used.

Note that the number of items used in the Hypothesized Means box and the Group Sample Size Pattern box is controlled by this number.

Examples:

3,4,5
4 5 6
3 to 11 by 2

Minimum Detectable Difference

Specify one or more values of the minimum detectable difference. This is the smallest difference between any two group means that is to be detectable by the experiment. Note that this is a positive amount. This value is set by the researcher to represent the smallest difference between two means that will be of practical significance to other researchers. Note that in the case of Dunnett’s test, this is the maximum difference between each treatment and the control.

Examples:

3
3 4 5
10 to 20 by 2
**Type of Multiple Comparison**

Specify the type of multiple comparison test to be analyzed. The tests available are

Tukey-Kramer: All possible paired comparisons.

Hsu Best: Constrained comparisons with the best.

Dunnett: Two-sided versus a control group.

**n (Sample Size Multiplier)**

This is the base, per-group sample size. One or more values separated by blanks or commas may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number by each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by \( m_1, m_2, m_3, \ldots, m_k \), and this value is represented by \( n \), the group sample sizes, \( N_1, N_2, N_3, \ldots, N_k \), are calculated as follows:

\[
N_1 = \lceil n(m_1) \rceil \\
N_2 = \lceil n(m_2) \rceil \\
N_3 = \lceil n(m_3) \rceil \\
\text{etc.,}
\]

where the operator, \( \lceil X \rceil \), means the next integer after \( X \), e.g. \( \lceil 3.1 \rceil = 4 \).

For example, suppose there are three groups, and the Group Sample Size Pattern is set to \( 1,2,3 \). If \( n \) is 5, the resulting sample sizes will be 5, 10, and 15. If \( n \) is 50, the resulting group sample sizes will be 50, 100, and 150. If \( n \) is set to \( 2,4,6,8,10 \), five sets of group sample sizes will be generated, and an analysis run for each. If the Group Sample Size Pattern is \( 1,2,3 \), these sets would be

\[
\begin{align*}
2 & \quad 4 & \quad 6 \\
4 & \quad 8 & \quad 12 \\
6 & \quad 12 & \quad 18 \\
8 & \quad 16 & \quad 24 \\
10 & \quad 20 & \quad 30 \\
\end{align*}
\]

As a second example, suppose there are three groups, and the Group Sample Size Pattern is \( 0.2,0.3,0.5 \). When the fractional Pattern values sum to one, \( n \) can be interpreted as the total sample size of all groups, and the Pattern values as the proportion of the total in each group.

If \( n \) is 10, the three group sample sizes would be 2, 3, and 5.

If \( n \) is 20, the three group sample sizes would be 4, 6, and 10.

If \( n \) is 12, the three group sample sizes would be

\[
(0.2)12 = 2.4, \text{ which is rounded up to the next whole integer, 3},
\]

\[
(0.3)12 = 3.6, \text{ which is rounded up to the next whole integer, 4},
\]

and \( (0.5)12 = 6 \).

Note that in this case, \( 3+4+6 \) does not equal \( n \) (which is 12). This can happen because of rounding.
Group Sample Size Pattern

A set of positive, numeric values (one for each group) is entered here. The sample size of group \( i \) is found by multiplying the \( i^{th} \) number from this list times the value of \( n \) and rounding up to the next whole number. The number of values must match the number of groups, \( k \). When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

Note that in the case of Dunnett’s test, the last group corresponds to the control group. Thus, if you want to study the implications of having a group with a different sample size for the control group, you should specify that sample size in the last position.

Equal

If all sample sizes are to be equal, enter “Equal” here and the desired sample size in \( n \). A set of \( k \) 1’s will be used. This will result in \( N1 = N2 = N3 = n \). That is, all sample sizes are equal to \( n \).

Alpha

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal means when in fact the means are equal. Values must be between zero and one. However, since alpha must be less than or equal to beta, the upper limit is beta, not one.

Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta

This option specifies one or more values for beta. In the case of multiple comparisons, power is the probability that the confidence intervals will cover the true parameter values and be sufficiently narrow to be useful. This is a modified definition of power; since beta equals 1-power, it is has a modified definition as well.

Values must be between zero and one. However, since alpha must be less than or equal to beta, the lower limit is alpha, not zero.

Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk you are willing to take.

Power is defined as 1-beta. Specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
S - Std Dev of Subjects
This option refers to $\sigma$, the standard deviation within a group. It represents the variability from subject to subject that occurs when the subjects are treated identically. It is assumed to be the same for all groups. This value is approximated in an analysis of variance table by the square root of the mean square error.

Since they are positive square roots, the numbers must be strictly greater than zero. You can press the SD button to obtain further help on estimating the standard deviation.

Note that if you are using this procedure to test a factor (such as an interaction) from a more complex design, the value of standard deviation is estimated by the square root of the mean square of the term that is used as the denominator in the $F$ test.

You can enter a list of values separated by blanks or commas, in which case a separate analysis will be calculated for each value.

Examples of valid entries:

1,4,7,10
1 4 7 10
1 to 10 by 3

Options Tab
The Options tab contains parameters that control the progress and termination of the iterative procedures.

Maximum Iterations
Specify the maximum number of iterations before the search for the criterion of interest is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank.

Search Precision
Specify the precision to be used in the routines that search for the value of the minimum detectable difference. Note that the closer this value is to zero, the longer a search will take.
Example1 - Calculating Power

An experiment is being designed to compare the means of four groups using the Tukey-Kramer pairwise multiple comparison test with a significance level of 0.05. Previous studies indicate that the standard deviation is 5.3. The typical mean response level is 63.4. The researcher believes that a 25% increase in the mean will be of interest to others. Since $0.25(63.4) = 15.85$, this is the number that will be used as the minimum detectable difference.

To better understand the relationship between power and sample size, the researcher wants to compute the power for several group sample sizes between 2 and 14. The sample sizes will be equal across all groups.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template 'Example1' by clicking the Template tab and loading this template.

Report Definitions
Power is the probability of rejecting a false null hypothesis. It should be close to one. 
n is the average group sample size. 
k is the number of groups. 
Total N is the total sample size of all groups. 
Alpha is the probability of rejecting a true null hypothesis. It should be small. 
Beta is the probability of accepting a false null hypothesis. It should be small. 
The Minimum Detectable Difference between any two group means. 
S is the within group standard deviation. 
The Diff / S is the ratio of Min. Detect. Diff. to standard deviation.

Summary Statements
In a single factor ANOVA study, sample sizes of 2, 2, 2, and 2 are obtained from the 4 groups 
whose means are to be compared. The total sample of 8 subjects achieves 1% power to detect a 
difference of at least 15.85 using the Tukey-Kramer (Pairwise) multiple comparison test at a 
0.0500 significance level. The common standard deviation within a group is assumed to be 5.30.

This report shows the numeric results of this power study. Following are the definitions of the 
columns of the report.

Power
This is the probability that the confidence intervals will cover the true parameter values and be 
sufficiently narrow to be useful.

Average n
The average of the group sample sizes.

k
The number of groups.

Total N
The total sample size of the study.

Alpha
The probability of rejecting a true null hypothesis. This is often called the significance level.

Beta
Equal to 1- power. Note the definition of power above.

Minimum Detectable Difference
This is the value of the minimum detectable difference. This is the minimum difference between 
two means that is thought to be of practical importance. Note that in the case of Dunnett’s test, 
this is the minimum difference between a treatment mean and the control mean that is of practical 
importance.

Standard Deviation (S)
This is the within-group standard deviation. It was set in the Data window.

Diff / S
This is an index of relative difference between the means standardized by dividing by the 
standard deviation. This value can be used to make comparisons among studies.

This report shows the details of each row of the previous report.

**Group**
The group identification number is shown on each line. The second to the last line represents the last group. When Dunnett’s test has been selected, this line represents the control group.

The last line, labeled *Total*, gives the total for all the groups.

**n**
This is the sample size of each group. This column is especially useful when the sample sizes are unequal.

**Percent n of Total N**
This is the percentage of the total sample that is allocated to each group.

**Alpha**
The probability of rejecting a true null hypothesis. This is often called the significance level.

**Power**
This is the probability that the confidence intervals will cover the true parameter values and be sufficiently narrow to be useful.

**Minimum Detectable Difference**
This is the value of the minimum detectable difference. This is the minimum difference between two means that is thought to be of practical importance. Note that in the case of Dunnett’s test, this is the minimum difference between a treatment mean and the control mean that is of practical importance.

**Standard Deviation (S)**
This is the within-group standard deviation. It was set in the Data window.
Plot Section

This plot gives a visual presentation to the results in the Numeric Report. We can see the impact on the power of increasing the sample size.

When you create one of these plots, it is important to use trial and error to find an appropriate range for the horizontal variable so that you have results with both low and high power.

Example 2 - Power after Dunnett’s Test

This example covers the situation in which you are calculating the power of Dunnett’s test on data that have already been collected and analyzed.

An experiment included a control group and two treatment groups. Each group had seven individuals. A single response was measured for each individual and recorded in the following table.

<table>
<thead>
<tr>
<th>Control</th>
<th>T1</th>
<th>T2</th>

<td>259.03</td>
<td></td>
</tr>
</tbody>
</table>

The significance level (Prob Level) was only 0.061—not enough for statistical significance. Since the lower confidence limits are negative and the upper confidence limits are positive, Dunnett’s two-sided test did not find a significant difference between either treatment and the control group.

The researcher had hoped to show that the treatment groups had higher response levels than the control group. He could see that the group means followed this pattern since the mean for T1 was about 25% higher than the control mean and the mean for T2 was about 23% higher than the control mean. He decided to calculate the power of the experiment.

Setup

The data entry for this problem is simple. The only entry that is not straightforward is finding an appropriate value for the standard deviation. Since the standard deviation is estimated by the square root of the mean square error, it is calculated as \( \sqrt{11541.3} = 107.4304 \).

You can enter these values yourself or load the Example2 template from the Template tab.

### Numeric Results

<table>
<thead>
<tr>
<th>Power</th>
<th>Average Size (n)</th>
<th>k</th>
<th>Total N</th>
<th>Alpha</th>
<th>Beta</th>
<th>Minimum Detectable Difference</th>
<th>Standard Deviation (S)</th>
<th>Diff / S</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0002</td>
<td>7.00</td>
<td>3</td>
<td>21</td>
<td>0.0500</td>
<td>0.9998</td>
<td>133.00</td>
<td>107.43</td>
<td>1.2380</td>
</tr>
</tbody>
</table>

The power is only 0.0002. Hence, there was little chance of detecting a difference of 133 between a treatment and a control group.

It was of interest to the researcher to determine how large of a sample was needed if the power was to be 0.90. Setting Beta equal to 0.90 and ‘Find/Solve For’ to $n$ resulted in the following report.

<table>
<thead>
<tr>
<th>Power</th>
<th>Average Size (n)</th>
<th>k</th>
<th>Total N</th>
<th>Alpha</th>
<th>Beta</th>
<th>Minimum Detectable Difference</th>
<th>Standard Deviation (S)</th>
<th>Diff / S</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.9042</td>
<td>33.00</td>
<td>3</td>
<td>99</td>
<td>0.0500</td>
<td>0.0958</td>
<td>133.00</td>
<td>107.43</td>
<td>1.2380</td>
</tr>
</tbody>
</table>

We see that instead of 7 per group, 33 per group were needed.

It was also of interest to the research to determine how large of a difference between the means could have been detected. Setting ‘Find’ to Min Detectable Difference resulted in the following report.

<table>
<thead>
<tr>
<th>Power</th>
<th>Average Size (n)</th>
<th>k</th>
<th>Total N</th>
<th>Alpha</th>
<th>Beta</th>
<th>Minimum Detectable Difference</th>
<th>Standard Deviation (S)</th>
<th>Diff / S</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.9000</td>
<td>7.00</td>
<td>3</td>
<td>21</td>
<td>0.0500</td>
<td>0.1000</td>
<td>348.81</td>
<td>107.43</td>
<td>3.2468</td>
</tr>
</tbody>
</table>

We see that a study of this size with these parameters could only detect a difference of 348.8. This explains why the results were not significant.
Example3 - Using Unequal Sample Sizes

It is usually advisable to design experiments with equal sample sizes in each group. In some cases, however, it may be necessary to allocate subjects unequally across the groups. This may occur when the group variances are unequal, the costs per subject are different, or the dropout rates are different. This module can be used to study the power of unbalanced experiments.

In this example which will use Dunnett’s test, the minimum detectable difference is 2.0, the standard deviation is 1.0, alpha is 0.05, and $k$ is 3. The sample sizes are 7, 7, and 14.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template Example3a by clicking the Template tab and loading this template.

Alternatively, this problem could have been set up as follows (Example3b):

$n$ (Sample Size Multiplier) ...............7
Group Sample Size Pattern ...............1 1 2

The advantage of this method is that you can try several values of $n$ while keeping the same allocation ratios.
Example 4 - Validation using Hsu

Hsu (1996) page 241 presents an example of determining the sample size in an experiment with 8 groups. The minimum detectable difference is 10,000 psi. The standard deviation is 3,000 psi. Alpha is 0.05 and beta is 0.10. He finds a sample size of 10 per group for the Tukey-Kramer test, a sample size of 8 for Hsu’s test, and a sample size of 8 for Dunnett’s test.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load and run each of the Example4 templates from the Template tab.

Option | Value
---|---
Data Tab
Find | n
k (Number of Groups) | 8

PASS found \( n = 8 \).
Example 5 - Validation using Pan and Kupper

Pan and Kupper (1999, page 1481) present examples of determining the sample size using alternative methods. It is interesting to compare the method of Hsu (1996) with theirs. Although the results are not exactly the same, they are very close.

In the example of Pan and Kupper, the minimum detectable difference is 0.50. The standard deviation is 0.50. Alpha is 0.05, and beta is 0.10. They find a sample size of 51 per group for Dunnett’s test and a sample size of 60 for the Tukey-Kramer test.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load and run each of the Example5 templates from the Template tab.

PASS also found $n = 62$. This is very close to the 60 that Pan and Kupper found using a slightly different method.
Chapter 580

Pair-Wise Multiple Comparisons using Simulation

Introduction

This procedure uses simulation analyze the power and significance level of three pair-wise multiple-comparison procedures: Tukey-Kramer, Kruskal-Wallis, and Games-Howell. For each scenario, two simulations are run: one estimates the significance level and the other estimates the power.

The term *multiple comparisons* refers to a set of two or more statistical hypothesis tests. The term *pair-wise multiple comparisons* refers to the set of all pairs of means that can be generated among the means of $k$ groups. For example, suppose the levels of a factor with five groups are labeled A, B, C, D, and E. The ten possible paired-comparisons that could be made among the five groups are A-B, A-C, A-D, A-E, B-C, B-D, B-E, C-D, C-E, and D-E.

As the number of groups increases, the number of comparisons (pairs) increases dramatically. For example, a 5 group design has 10 pairs, a 10 group design has 45 pairs, and a 20 group design has 190 pairs. When several comparisons are made among the group means, the determination of the significance level of each individual comparison is much more complex because of the problem of *multiplicity*. *Multiplicity* here refers to the fact that the chances of making at least one incorrect decision increases as the number of statistical tests increases. The method of *multiple comparisons* has been developed to account for this multiplicity.
Error Rates
When dealing with several simultaneous statistical tests, both individual-wise and experiment wise error rates should be considered.

1. **Comparison-wise error rate.** This is the probability of a type-I error (rejecting a true H0) for a particular test. In the case of the five-group design, there are ten possible comparison-wise error rates, one for each of the ten possible pairs. We will denote this error rate $\alpha_c$.

2. **Experiment-wise (or family-wise) error rate.** This is the probability of making one or more type-I errors in the set (family) of comparisons. We will denote this error rate $\alpha_f$.

The relationship between these two error rates when the tests are independent is given by

$$\alpha_f = 1 - (1 - \alpha_c)^C$$

where $C$ is the total number of comparisons in the family. For example, if $\alpha_c$ is 0.05 and $C$ is 10, $\alpha_f$ is 0.401. There is about a 40% chance that at least one of the ten pairs will be concluded to be different when in fact they are all the same. When the tests are correlated, as they are among a set of pair-wise comparisons, the above formula provides an upper bound to the family-wise error rate.

The techniques described below provide control for $\alpha_f$ rather than $\alpha_c$. 
Technical Details

The One-Way Analysis of Variance Design

The discussion that follows is based on the common one-way analysis of variance design which may be summarized as follows. Suppose the responses \( Y_i \) in \( k \) groups each follow a normal distribution with means \( \mu_1, \mu_2, \ldots, \mu_k \) and unknown variance \( \sigma^2 \). Let \( n_1, n_2, \ldots, n_k \) denote the number of subjects in each group.

The analysis of these responses is based on the sample means

\[
\hat{\mu}_i = \bar{Y}_i = \frac{n_i}{\sum_{i=1}^{k} n_i} \sum_{j=1}^{n_i} Y_{ij}
\]

and the pooled sample variance

\[
\hat{\sigma}^2 = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2}{\sum_{i=1}^{k} (n_i - 1)}
\]

The \( F \) test is the usual method of analysis of the data from such a design, testing whether all of the means are equal. However, a significant \( F \) test does not indicate which of the groups are different, only that at least one is different. The analyst is left with the problem of determining which of the groups are different and by how much.

The Tukey-Kramer procedure, the Kruskal-Wallis procedure, and the Games-Howell procedure are the pair-wise multiple-comparison procedures that have been developed for this situation. The calculation of each of these tests is given next.

Tukey-Kramer

This test is referenced in Kirk (1982). It uses the critical values from the studentized-range distribution. For each pair of groups, the significance test between any two groups \( i \) and \( j \) is calculated by rejecting the null hypothesis of mean equality if

\[
\frac{\left| \bar{Y}_i - \bar{Y}_j \right|}{\sqrt{\frac{\hat{\sigma}^2}{2} \left( \frac{1}{n_i} + \frac{1}{n_j} \right)}} \geq q_{\alpha, k, v}
\]

where

\[
v = \sum_{i=1}^{k} n_i - k = N - k
\]
Kruskal-Wallis
This test is attributed to Dunn (1964) and is referenced in Gibbons (1976). It is a nonparametric, or distribution-free, test for which the assumption of normality is not necessary. It tests whether pairs of medians are equal using a rank test. Sample sizes of at least five (but preferably larger) for each treatment are recommended for use of this test. The error rate is adjusted on a comparison-wise basis to give the experiment-wise error rate, $\alpha_f$. Instead of using means, it uses average ranks, as the following formula indicates, with $\alpha = \alpha_f / (k(k-1))$. For each pair of groups, $i$ and $j$, the null hypothesis of equality is rejected if

$$\frac{|R_i - R_j|}{\sqrt{\frac{n(n+1)}{12}\left(\frac{1}{n_i} + \frac{1}{n_j}\right)}} \geq z_\alpha$$

Note that, when necessary, the usual adjustment for ties is made.

Games-Howell
This test is referenced in Kirk (1982) page 120. It was developed for the case when the individual group variances cannot be assumed to be equal. It also uses critical values from the studentized-range distribution. For each pair of groups, $i$ and $j$, the null hypothesis of equality is rejected if

$$\frac{|\bar{Y}_i - \bar{Y}_j|}{\sqrt{\frac{1}{2}\left(\hat{\sigma}_i^2/n_i + \hat{\sigma}_j^2/n_j\right)}} \geq q_{\alpha_f,k,v'}$$

where

$$v' = \frac{\left(\frac{\hat{\sigma}_i^2}{n_i} + \frac{\hat{\sigma}_j^2}{n_j}\right)^2}{\frac{\hat{\sigma}_i^4}{n_i(n_i-1)} + \frac{\hat{\sigma}_j^4}{n_j(n_j-1)}}$$

If any of the following conditions hold, then $v' = n_i + n_j - 2$:

1. $9/10 \leq n_i / n_j \leq 10/9$
2. $9/10 \leq \left(\frac{\hat{\sigma}_i^2}{n_i}\right) / \left(\frac{\hat{\sigma}_j^2}{n_j}\right) \leq 10/9$
3. $4/5 \leq n_i / n_j \leq 5/4$ and $1/2 \leq \left(\frac{\hat{\sigma}_i^2}{n_i}\right) / \left(\frac{\hat{\sigma}_j^2}{n_j}\right) \leq 2$
4. $2/3 \leq n_i / n_j \leq 3/2$ and $3/4 \leq \left(\frac{\hat{\sigma}_i^2}{n_i}\right) / \left(\frac{\hat{\sigma}_j^2}{n_j}\right) \leq 4/3$
Definition of Power for Multiple Comparisons

The notion of the power of a test is well-defined for individual tests. Power is the probability of rejecting a false null hypothesis. However, this definition does not extend easily when there are a number of simultaneous tests.

To understand the problem, consider an experiment with three groups labeled, A, B, and C. There are three paired comparisons in this experiment: A-B, A-C, and B-C. How do we define power for these three tests? One approach would be to calculate the power of each of the three tests, ignoring the other two. However, this ignores the interdependence among the three tests. Other definitions of the power of the set of tests might be the probability of detecting at least one of the differing pairs, exactly one of the differing pairs, at least two of the differing pairs, and so on. As the number of pairs increases, the number of possible definitions of power also increases. The two definitions that we emphasize in PASS were recommended by Ramsey (1978). They are any-pair power and all-pairs power. Other design characteristics, such as average-comparison power and false-discovery rate, are important to consider. However, our review of the statistical literature resulted in our focus on these two definitions of power.

Any-Pair Power
Any-pair power is the probability of detecting at least one of the pairs that are actually different.

All-Pairs Power
All-pairs power is the probability of detecting all of the pairs that are actually different.

Simulation Details

Computer simulation allows us to estimate the power and significance level that is actually achieved by a test procedure in situations that are not mathematically tractable. Computer simulation was once limited to mainframe computers. But, in recent years, as computer speeds have increased, simulation studies can be completed on desktop and laptop computers in a reasonable period of time.

The steps to a simulation study are

1. Specify how each test is to be carried out. This includes indicating how the test statistic is calculated and how the significance level is specified.

2. Generate random samples from the distributions specified by the alternative hypothesis. Calculate the test statistics from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the power of each test.

3. Generate random samples from the distributions specified by the null hypothesis. Calculate each test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the significance level of each test.

4. Repeat steps 2 and 3 several thousand times, tabulating the number of times the simulated data leads to a rejection of the null hypothesis. The power is the proportion of simulated samples in step 2 that lead to rejection. The significance level is the proportion of simulated samples in step 3 that lead to rejection.
Generating Random Distributions

Two methods are available in *PASS* to simulate random samples. The first method generates the random variates directly, one value at a time. The second method generates a large pool (over 10,000) of random values and then draws the random numbers from this pool. This second method can cut the running time of the simulation by 70%!

As mentioned above, the second method begins by generating a large pool of random numbers from the specified distributions. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is the maximum of twice the number of simulated samples desired and 10,000.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for: power or sample size (n). If you choose to solve for n, you must choose the type of power you want to solve for: any-pair power or all-pairs power. The value of the option Power will then represent this type of power.

*Any-pair power* is the probability of detecting at least one pair from among those that are actually different. *All-pairs power* is the probability of detecting all pairs that are actually different.

Note that the search for n may take several minutes because a separate simulation must be run for each trial value of n. You may find it quicker and more informative to solve for the Power for a range of sample sizes.

Simulations

This option specifies the number of iterations, M, used in the simulation. As the number of iterations is increased, the running time and accuracy are increased as well.

The precision of the simulated power estimates are calculated using the binomial distribution. Thus, confidence intervals may be constructed for various power values. The following table gives an estimate of the precision that is achieved for various simulation sizes when the power is either 0.50 or 0.95. The table values are interpreted as follows: a 95% confidence interval of the true power is given by the power reported by the simulation plus and minus the ‘Precision’ amount given in the table.

<table>
<thead>
<tr>
<th>Simulation Size (M)</th>
<th>Precision when Power = 0.50</th>
<th>Precision when Power = 0.95</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.100</td>
<td>0.044</td>
</tr>
<tr>
<td>500</td>
<td>0.045</td>
<td>0.019</td>
</tr>
<tr>
<td>1000</td>
<td>0.032</td>
<td>0.014</td>
</tr>
<tr>
<td>2000</td>
<td>0.022</td>
<td>0.010</td>
</tr>
<tr>
<td>5000</td>
<td>0.014</td>
<td>0.006</td>
</tr>
<tr>
<td>10000</td>
<td>0.010</td>
<td>0.004</td>
</tr>
<tr>
<td>50000</td>
<td>0.004</td>
<td>0.002</td>
</tr>
<tr>
<td>100000</td>
<td>0.003</td>
<td>0.001</td>
</tr>
</tbody>
</table>

Notice that a simulation size of 1000 gives a precision of plus or minus 0.01 when the true power is 0.95. Also note that as the simulation size is increased beyond 5000, there is only a small amount of additional accuracy achieved.
FWER (Alpha)
This option specifies one or more values of the family-wise error rate (FWER) which is the analog of alpha for multiple comparisons. FWER is the probability of falsely detecting (concluding that the means are different) at least one comparison for which the true means are the same. For independent tests, the relationship between the individual-comparison error rate (ICER) and FWER is given by the formulas

\[ FWER = 1 - (1 - ICER)^C \]

or

\[ ICER = 1 - (1 - FWER)^{(1/C)} \]

where \(^n\) represents exponentiation (as in \(4^2 = 16\)) and \(C\) represents the number of comparisons. For example, if \(C = 5\) and \(FWER = 0.05\), then \(ICER = 0.0102\). Thus, the individual comparison tests must be conducted using a Type-1 error rate of 0.0102, which is much lower than the family-wise rate of 0.05.

The popular value for FWER remains at 0.05. However, if you have a large number of comparisons, you might decide that a larger value, such as 0.10, is appropriate.

Power
This option is only used when Find (Solve For) is set to \(n\) (All-Pairs) or \(n\) (Any-Pair).

Power is defined differently with multiple comparisons. Although many definitions are possible, two are adopted here. Any-pair power is the probability of detecting at least one pair of the means that are different. All-pairs power is the probability of detecting all pairs of means that are truly different. As the number of groups is increased, these power probabilities will decrease because more tests are being conducted.

Since this is a probability, the range is between 0 and 1. Most researchers would like to have the power at least at 0.8. However, this may require extremely large sample sizes when the number of tests is large.
n (Sample Size Multiplier)

This is the base, per group, sample size. One or more values separated by blanks or commas may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number by each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by

$m_1, m_2, m_3, \ldots, m_g$

and this value is represented by $n$, the group sample sizes $n_1, n_2, n_3, \ldots, n_g$ are calculated as follows:

$n_1 = \lfloor n(m_1) \rfloor$

$n_2 = \lfloor n(m_2) \rfloor$

$n_3 = \lfloor n(m_3) \rfloor$

etc.

where the operator, $\lfloor X \rfloor$ means the next integer after $X$, e.g. $\lfloor 3.1 \rfloor = 4$. This is required because sample sizes must be whole numbers.

For example, suppose there are three groups and the Group Sample Size Pattern is set to $1,2,3$. If $n$ is 5, the resulting sample sizes will be 5, 10, and 15. If $n$ is 50, the resulting group sample sizes will be 50, 100, and 150. If $n$ is set to $2,4,6,8,10$; five sets of group sample sizes will be generated and an analysis run for each. These sets are:

2  4  6
4  8  12
6 12 18
8 16 24
10 20 30

As a second example, suppose there are three groups and the Group Sample Size Pattern is $0.2,0.3,0.5$. When the fractional Pattern values sum to one, $n$ can be interpreted as the total sample size $N$ of all groups and the Pattern values as the proportion of the total in each group.

If $n$ is 10, the three group sample sizes would be 2, 3, and 5.

If $n$ is 20, the three group sample sizes would be 4, 6, and 10.

If $n$ is 12, the three group sample sizes would be

$(0.2)12 = 2.4$ which is rounded up to the next whole integer, 3.

$(0.3)12 = 3.6$ which is rounded up to the next whole integer, 4.

$(0.5)12 = 6$.

Note that in this case, $3+4+6$ does not equal $n$ (which is 12). This can happen because of rounding.
**Group Sample Size Pattern**

The purpose of the group sample size pattern is to allow several groups with the same sample size to be generated without having to type each individually.

A set of positive, numeric values (one for each row of distributions) is entered here. Each item specified in this list applies to the whole row of distributions. For example, suppose the entry is 1 2 1 and Grps 1 = 3, Grps 2 = 1, Grps 3 = 2. The sample size pattern used would be 1 1 2 1 1.

The sample size of group $i$ is found by multiplying the $i^{th}$ number from this list by the value of $n$ and rounding up to the next whole number. The number of values must match the number of groups, $g$. When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

**Equal**

If all sample sizes are to be equal, enter *Equal* here and the desired sample size in $n$. A set of $g$ 1’s will be used. This will result in $n_1 = n_2 = \ldots = n_g = n$. That is, all sample sizes are equal to $n$.

**MC Procedure**

Specify which pair-wise multiple comparison procedure is to be reported from the simulations. The choices are

- **Tukey-Kramer**
  This is the most popular and the most often recommended.

- **Kruskal-Wallis**
  This is recommended when a nonparametric procedure is wanted.

- **Games-Howell**
  This is recommended when the variances of the groups are unequal.

**Specifying Simulation Distributions**

These options specify the distributions to be used in the two simulations, one set per row. The first option specifies the number of groups represented by the two distributions that follow. The second option specifies the distribution to be used in simulating the null hypothesis to determine the significance level (alpha). The third option specifies the distribution to be used in simulating the alternative hypothesis to determine the power.

**Grps i (i = 1 to 9)**

This value specifies the number of groups specified by the H0 and H1 distribution statements to the right. Usually, you will enter ‘1’ to specify a single H0 and a single H1 distribution, or you will enter ‘0’ to indicate that the distributions specified on this line are to be ignored. This option lets you specify many identical distributions with a single phrase.

The total number of groups $g$ is equal to the sum of the values for the three rows of distributions shown under the Data1 tab and the six rows of distributions shown under the Data2 tab.

Note that each item specified in the *Group Sample Size Pattern* option applies to the whole row of entries here. For example, suppose the *Group Sample Size Pattern* was 1 2 1 and Grps 1 = 3, Grps 2 = 1, and Grps 3 = 2. The sample size pattern would be 1 1 2 1 1 1.

Note that since the first group is the control group, the value for Grps 1 is usually set to one.
**Group i Distribution(s) | H0**

This entry specifies the distribution of one or more groups under the null hypothesis, H0. The magnitude of the differences of the means of these distributions, which is often summarized as the standard deviation of the means, represents the magnitude of the mean differences specified under H0. Usually, the means are assumed to be equal under H0, so their standard deviation should be zero except for rounding.

These distributions are used in the simulations that estimate the actual significance level. They also specify the value of the mean under the null hypothesis, H0. Usually, these distributions will be identical. The parameters of each distribution are specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value \( M_0 \) is reserved for the value of the mean under the null hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean is entered first.

- Beta = A(M0, A, B, Minimum)
- Binomial = B(M0, N)
- Cauchy = C(M0, Scale)
- Constant = K(Value)
- Exponential = E(M0)
- F = F(M0, DF1)
- Gamma = G(M0, A)
- Multinomial = M(P1, P2, …, Pk)
- Normal = N(M0, SD)
- Poisson = P(M0)
- Student’s T = T(M0, D)
- Tukey’s Lambda = L(M0, S, Skewness, Elongation)
- Uniform = U(M0, Minimum)
- Weibull = W(M0, B)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

**Finding the Value of the Mean of a Specified Distribution**

Except for the multinomial distribution, the distributions have been parameterized in terms of their means since this is the parameter being tested. The mean of a distribution created as a linear combination of other distributions is found by applying the linear combination to the individual means. However, the mean of a distribution created by multiplying or dividing other distributions is not necessarily equal to applying the same function to the individual means. For example, the mean of \( 4N(4, 5) + 2N(5, 6) \) is \( 4*4 + 2*5 = 26 \), but the mean of \( 4N(4, 5) * 2N(5, 6) \) is not exactly \( 4*4*2*5 = 160 \) (although it is close).
Group i Distribution(s) | H1

Specify the distribution of this group under the alternative hypothesis, H1. This distribution is used in the simulation that determines the power. A fundamental quantity in a power analysis is the amount of variation among the group means. In fact, classical power analysis formulas, this variation is summarized as the standard deviation of the means.

The important point to realize is that you must pay particular attention to the values you give to the means of these distributions because they are fundamental to the interpretation of the simulation.

For convenience in specifying a range of values, the parameters of the distribution can be specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value \( M1 \) is reserved for the value of the mean under the alternative hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean, M1, is entered first.

- Beta = A(M1, A, B, Minimum)
- Binomial = B(M1, N)
- Cauchy = C(M1, Scale)
- Constant = K(Value)
- Exponential = E(M1)
- F = F(M1, DF1)
- Gamma = G(M1, A)
- Multinomial = M(P1, P2, ..., Pk)
- Normal = N(M1, SD)
- Poisson = P(M1)
- Student's T = T(M1, D)
- Tukey's Lambda = L(M1, S, Skewness, Elongation)
- Uniform = U(M1, Minimum)
- Weibull = W(M1, B)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

M0 (Mean | H0)

These values are substituted for \( M0 \) in the distribution specifications given above. \( M0 \) is intended to be the value of the mean hypothesized by the null hypothesis, H0.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.

M1 (Mean | H1)

These values are substituted for \( M1 \) in the distribution specifications given above. Although it can be used wherever you want, \( M1 \) is intended to be the value of the mean hypothesized by the alternative hypothesis, H1.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.
Parameter Values (S, A, B, C)
Enter the numeric value(s) of the parameters listed above. These values are substituted for the corresponding letter in all four distribution specifications.

You can enter a list of values for each letter using the syntax 0 1 2 3 or 0 to 3 by 1.
You can also change the letter that is used as the name of this parameter using the pull-down menu to the side.

Minimum Difference
Specify the smallest difference between any two means that is to be detectable by the experiment. Pairs with mean differences smaller than this amount are to be considered equal.

Options Tab
The Options tab contains limits on the number of iterations and various options about individual tests.

Maximum Iterations
Specify the maximum number of iterations before the search for the sample size is aborted. When the maximum number of iterations is reached without convergence, the sample size is left blank. We recommend a value of at least 500.

Random Number Pool Size
This is the size of the pool of values from which the random samples will be drawn. Pools should be at least the maximum of 10,000 and twice the number of simulations. You can enter Automatic and an appropriate value will be calculated.
If you do not want to draw numbers from a pool, enter 0 here.

Reports Tab
The Reports tab contains settings about the format of the output.

Show Various Reports & Plots
These options let you specify whether you want to generate the standard reports and plots.

Show Inc’s & 95% C.I.
Checking this option causes an additional line to be printed showing a 95% confidence interval for both the power and actual alpha and half the width of the confidence interval (the increment).

Show Comparative Reports & Plots
These options let you specify whether you want to generate reports and plots that compare the test statistics that are available.
Example 1 - Power at Various Sample Sizes

An experiment is being designed to investigate the variety of response when an experiment is replicated under five different conditions. Previous studies have shown that the standard deviation within a group is 3.0. Researchers want to detect a shift in the mean of 3.0 or more. To accomplish this, they set the means of the first four groups to zero and the mean of the fifth group to 3.0. They want to investigate sample sizes of 5, 10, 15, and 20 subjects per group.

Although they will conduct an F-test on the data, their primary analysis will be a set of Tukey-Kramer multiple comparison tests. They set the FWER to 0.05.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

#### Summary of Simulations Report Definitions
- **H0**: the null hypothesis that each pair of group means are equal.
- **H1**: the alternative hypothesis that at least one pair of group means are not equal.
- **All-Pairs Power**: the estimated probability of detecting all unequal pairs.
- **Any-Pairs Power**: the estimated probability of detecting at least one unequal pair.
- **n**: the average of the group sample sizes.
- **N**: the combined sample size of all groups.
- **Family-Wise Error Rate (FWER)**: the probability of detecting at least one equal pair assuming H0.
- **Target FWER**: the user-specified FWER.
- **Actual FWER**: the FWER estimated by the alpha simulation.
- **Sm|H1**: the standard deviation of the group means under H1.
- **SD|H1**: the pooled, within-group standard deviation under H1.
- **Second Row**: provides the precision and a confidence interval based on the size of the simulation for Any-Pairs Power, All-Pairs Power, and FWER. The format is (Precision) [95% LCL and UCL Alpha].

#### Summary Statements
A one-way design with 5 groups has an average group sample size of 5.0 for a total sample size of 25. This design achieved an any-pair power of 0.2505 and an all-pair power of 0.0135 using the Tukey-Kramer M.C. Test with a target family-wise error rate of 0.050 and an actual target family-wise error rate 0.043. The average within group standard deviation assuming the alternative distribution is 3.0. These results are based on 2000 Monte Carlo samples from the null distributions: N(M0 S); N(M0 S); N(M0 S); N(M0 S); and N(M0 S) and the alternative distributions: N(M0 S); N(M0 S); N(M0 S); and N(M1 S). Other parameters used in the simulation were: M0 = 0.0, M1 = 3.0, and S = 3.0.

This report shows the estimated any-pairs power, all-pairs power, and FWER for each scenario. The second row shows three 95% confidence intervals in brackets: the first for the any-pairs power, the second for the all-pairs power, and the third for the FWER. Half the width of each confidence interval is given in parentheses as a fundamental measure of the precision of the simulation. As the number of simulations is increased, the width of the confidence intervals will decrease.

#### Any-Pairs Power
This is the probability of detecting any of the significant pairs. This value is estimated by the simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the estimated power.
All-Pairs Power
This is the probability of detecting all of the significant pairs. This value is estimated by the simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the estimated power.

Group Sample Size n
This is the average of the individual group sample sizes.

Total Sample Size N
This is the total sample size of the study.

S.D. of Means Sm|H1
This is the standard deviation of the hypothesized means of the alternative distributions. Under the null hypothesis, this value is zero. This value represents the magnitude of the difference among the means that is being tested. It is roughly equal to the average difference between the group means and the overall mean.

Note that the effect size is the ratio of Sm|H1 and SD|H1.

S.D. of Data SD|H1
This is the within-group standard deviation calculated from samples from the alternative distributions.

Actual FWER
This is the value of FWER (family-wise error rate) estimated by the simulation using the H0 distributions. It should be compared with the Target FWER to determine if the test procedure is accurate.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the Actual FWER.

Target FWER
This is the target value of FWER that was set by the user.

M0
This is the value entered for M0, the group means under H0.

M1
This is the value entered for M1, the group means under H1.

S
This is the value entered for S, the standard deviation.

</table>

This report shows the results of the H0 simulation. This simulation uses the H0 settings for each group. Its main purpose is to provide an estimate of the FWER.

### No. of Equal Pairs
Since under H0 all means are equal, this is the number of unique pairs of the groups. Thus, this is the number of pair-wise multiple comparisons.

### Mean No. of Type-1 Errors
This is the average number of type-1 errors (false detections) per set (family).

### Prop. Type-1 Errors
This is the proportion of type-1 errors (false detections) among all tests that were conducted.

### Prop. (No. of Type-1 Errors >0) FWER
This is the proportion of the H0 simulations in which at least one type-1 error occurred. This is called the family-wise error rate.

### Target FWER
This is the target value of FWER that was set by the user.

### Mean Pairs Alpha
Alpha is the probability of rejecting H0 when H0 is true. It is a characteristic of an individual test. This is the average alpha value over all of the tests in the family.

### Min Pairs Alpha
This is the minimum of all of the individual comparison alphas.

### Max Pairs Alpha
This is the maximum of all of the individual comparison alphas.

This report shows the results of the H1 simulation. This simulation uses the H1 settings for each group. Its main purpose is to provide an estimate of the power.

**No. of Equal Pairs/Unequal Pairs**
The first value is the number of pairs for which the means were equal under H1. The second value is the number of pairs for which the means were different under H1.

**Mean No. False Positives**
This is the average number of equal pairs that were declared as being unequal by the testing procedure. A *false positive* is a type-1 (alpha) error.

**Mean No. False Negatives**
This is the average number of unequal pairs that were not declared as being unequal by the testing procedure. A *false negative* is a type-2 (beta) error.

**Prop. Errors**
This is the proportion of type-1 and type-2 errors.

**Prop. Equal that were Detect.**
This is the proportion of the equal pairs in the H1 simulations that were declared as unequal.

**Prop. Uneq. that were Undet.**
This is the proportion of the unequal pairs in the H1 simulations that were not declared as being unequal.

**Prop. Detect. that were Equal (FDR)**
This is the proportion of all detected pairs in the H1 simulations that were actually equal. This is often called the *false discovery rate*.

**Prop. Undet. that were Uneq.**
This is the proportion of undetected pairs in the H1 simulations that were actually unequal.

**All Uneq. Pairs Power**
This is the probability of detecting all of the pairs that were different in the H1 simulation.

**Any Uneq. Pairs Power**
This is the probability of detecting any of the pairs that were different in the H1 simulation.
Mean, Min, and Max Pairs Power

These items give the average, the minimum, and the maximum of the individual comparison powers from the H1 simulation.

This report shows details of each row of the previous reports.

Hypo. Type

This indicates which simulation is being reported on each row. H0 represents the null simulation and H1 represents the alternative simulation.

Groups

Each group in the simulation is assigned a number. This item shows the arbitrary group number that was assigned.
Group Labels
These are the labels that were used in the individual alpha-level reports.

n/N
n is the average sample size of the groups. N is the total sample size across all groups.

Group Mean
These are the means of the individual groups as specified for the H0 and H1 simulations.

Ave. S.D.
This is the average standard deviation of all groups reported on each line. Note that it is calculated from the simulated data.

Simulation Model
This is the distribution that was used to simulate data for the groups reported on each line.

Individual pairwise powers from the H1 (Power) simulation are shown in the upper-right section. Individual pairwise significance levels from the H0 (Alpha) simulation are shown in the lower-left section.

* Starred values are the powers of pairs that are unequal under H1.

This report shows the individual probabilities of rejecting each pair. When a pair was actually different, the value is the power of that test. These power values are starred.
The results shown on the upper-right section of each simulation report are from the H1 simulation. The results shown on the lower-left section of the report are from the H0 simulation.

**Plot Section**

![Plot of All-Pair Power vs n](image1)

![Plot of Any-Pair Power vs n](image2)

These plots give a visual presentation of the all-pairs power values and the any-pair power values.
Example2 - Comparative results

Continuing with Example1, the researchers want to study the characteristics of alternative multiple comparison procedures.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example2 template from the Template tab.

These reports show the power and FWER of each of the three multiple comparison procedures. In these simulations of groups from the normal distributions with equal variances, we see that the Tukey-Kramer procedure is the champion.
Example 3 - Validation using Ramsey

Ramsey (1978) presents the results of a simulation study that compared the all-pair power of several different multiple comparison procedures. On page 483 of this article, he presents the results of a simulation in which there were four groups: two with means of -0.7 and two with means of 0.7. The standard deviation was 1.0 and the FWER was 0.05. Tukey’s multiple comparison procedure was used in the simulation. The sample size was 16 per group. Using a simulation of 1000 iterations, the all-pairs power was calculated as 0.723. Note that a confidence interval for this estimated all-pairs power is (0.703 to 0.759).

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

Note that the value found by PASS of 0.729 is very close to the value of 0.723 found by Ramsey (1978). More importantly, the value found by PASS is inside the confidence limits of Ramsey’s study.

We ran the simulation five more times and obtained 0.727, 0.723, 0.714, 0.740, and 0.732. We also ran the simulation with 10,000 iterations and obtained a power of 0.736 with a confidence interval of (0.727 to 0.745).
Example4 - Selecting a multiple comparison procedure when the data contain outliers

This example will investigate the impact of outliers on the power and precision of the various multiple comparison procedures when there are five groups.

A mixture of two normal distributions will be used to randomly generate outliers. The mixture will draw 95% of the data from a normal distribution with mean zero and variance one. The other 5% of the data will come from a normal distribution with mean zero and variance that ranges from one to ten. In the alternative distributions, two will have means of zero and the other three will have means of one.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example4 template from the Template tab.

These reports show the power and FWER of each of the three multiple comparison procedures. We note that when the variances are equal (A = 1), the Tukey-Kramer procedure performs only slightly better than the others. However, as the number of outliers is increased, the Kruskal-Wallis procedure emerges as the better choice. Also note that in the case with many outliers (Simulation 3), the FWER of all procedures is below the target value.
Chapter 585

Multiple Comparisons of Treatments versus a Control using Simulation

Introduction

This procedure uses simulation to analyze the power and significance level of two multiple-comparison procedures that perform two-sided hypothesis tests of each treatment group mean versus the control group mean using simulation. These are Dunnett’s test and the Kruskal-Wallis test. For each scenario, two simulations are run: one estimates the significance level and the other estimates the power.

The term *multiple comparisons of treatments versus a control* refers to the set of comparisons of each treatment group to a control group. If there are \( k \) groups of which \( k-1 \) are treatment groups, there will be \( k-1 \) tests.

When several comparisons are made among the group means, the interpretation for each comparison becomes more complex because of the problem of *multiplicity*. *Multiplicity* here refers to the fact that the chances of making at least one incorrect decision increases as the number of statistical tests increases. The method of *multiple comparisons* has been developed to account for this multiplicity.
Error Rates
When dealing with several simultaneous statistical tests, both individual-wise and experiment-wise error rates should be considered.

1. **Comparison-wise error rate.** This is the probability of a type-I error (rejecting a true H0) for a particular test. In the case of the five-group design, there are ten possible comparison-wise error rates, one for each of the ten possible pairs. We will denote this error rate $\alpha_c$.

2. **Experiment-wise (or family-wise) error rate.** This is the probability of making one or more type-I errors in the set (family) of comparisons. We will denote this error rate $\alpha_f$.

The relationship between these two error rates when the tests are independent is given by

$$\alpha_f = 1 - (1 - \alpha_c)^C$$

where $C$ is the total number of comparisons in the family. For example, if $\alpha_c$ is 0.05 and $C$ is 10, $\alpha_f$ is 0.401. There is about a 40% chance that at least one of the ten pairs will be concluded to be different when in fact they are all the same. When the tests are correlated, as they are among a set of pair-wise comparisons, the above formula provides an upper bound to the family-wise error rate.

The techniques described below provide control for $\alpha_f$ rather than $\alpha_c$. 
Technical Details

The One-Way Analysis of Variance Design

The discussion that follows is based on the common one-way analysis of variance design which may be summarized as follows. Suppose the responses $Y_i$ in $k$ groups each follow a normal distribution with means $\mu_1, \mu_2, \ldots, \mu_k$ and unknown variance $\sigma^2$. Let $n_1, n_2, \ldots, n_k$ denote the number of subjects in each group. The control group is assumed to be group one.

The analysis of these responses is based on the sample means

$$\hat{\mu}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} Y_{ij}$$

and the pooled sample variance

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y})^2}{\sum_{i=1}^{k} (n_i - 1)}$$

The $F$ test is the usual method of analysis of the data from such a design, testing whether all of the means are equal. However, a significant $F$ test does not indicate which of the groups are different, only that at least one is different. The analyst is left with the problem of determining which of the groups are different and by how much.

The Dunnett procedure and a special version of the Kruskal-Wallis procedure have been developed for this situation. The calculation of each of these tests is given next.

Dunnett’s Test

Dunnett (1955) developed a test procedure for simultaneously comparing each treatment with a control group. It uses the critical values of a special $t$ distribution given in Dunnett (1955). For each treatment and control pair, the significance test is calculated by rejecting the null hypothesis of mean equality if

$$\frac{|\bar{Y}_i - \bar{Y}_1|}{\sqrt{\hat{\sigma}^2 \left( \frac{1}{n_i} + \frac{1}{n_t} \right)}} \geq t_{Dunnett}^{1-\alpha/2, k, N-k} \quad i = 2, \ldots, k$$
Kruskal-Wallis Test

This test is attributed to Dunn (1964) and is referenced in Gibbons (1976). It is a nonparametric, or distribution-free, test which means that normality is not assumed. It tests whether the medians of each treatment-control pair are equal using a rank test. Sample sizes of at least five (but preferably larger) for each treatment are recommended for the use of this test. The error rate is adjusted on a comparison-wise basis to give the experiment-wise error rate, \( \alpha_f \). Instead of using means, it uses average ranks as the following formula indicates, with \( \alpha = \alpha_f / (2(k-1)) \). For each treatment and control pair, the significance test is calculated by rejecting the null hypothesis of median equality if

\[
\frac{\frac{\sum R_i - \sum R_i}{N(N+1)(\frac{1}{n_i} + \frac{1}{n_j})}}{\sqrt{\frac{12}{N(N+1)^2}} \geq z_{\alpha} \quad i = 2,\ldots,k}
\]

Note that, when necessary, the usual adjustment for ties is made.

Definition of Power for Multiple Comparisons

The notion of the power of a test is well-defined for individual tests. Power is the probability of rejecting a false null hypothesis. However, this definition does not extend easily when there are a number of simultaneous tests.

To understand the problem, consider an experiment with four groups labeled, C, A, B, and D. Suppose C is the control group. There are three paired comparisons in this experiment: A-C, B-C, and D-C. How do we define power for these three tests? One approach would be to calculate the power of each of the three tests, ignoring the other two. However, this ignores the interdependence among the three tests. Other definitions of the power of the set of tests might be the probability of detecting at least one of the differing pairs, exactly one of the differing pairs, at least two of the differing pairs, and so on. As the number of pairs increases, the number of possible definitions of power also increases. The two definitions that we emphasize in PASS were recommended by Ramsey (1978). They are any-pair power and all-pairs power. Other design characteristics, such as average-comparison power and false-discovery rate, are important to consider. However, our review of the statistical literature resulted in our focus on these two definitions of power.

Any-Pair Power

Any-pair power is the probability of detecting at least one of the pairs that are actually different.

All-Pairs Power

All-pairs power is the probability of detecting all of the pairs that are actually different.
Simulation Details

Computer simulation allows us to estimate the power and significance level that is actually achieved by a test procedure in situations that are not mathematically tractable. Computer simulation was once limited to mainframe computers. But, in recent years, as computer speeds have increased, simulation studies can be completed on desktop and laptop computers in a reasonable period of time.

The steps to a simulation study are

1. Specify how each test is to be carried out. This includes indicating how the test statistic is calculated and how the significance level is specified.

2. Generate random samples from the distributions specified by the alternative hypothesis. Calculate the test statistics from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the power of each test.

3. Generate random samples from the distributions specified by the null hypothesis. Calculate each test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the significance level of each test.

4. Repeat steps 2 and 3 several thousand times, tabulating the number of times the simulated data leads to a rejection of the null hypothesis. The power is the proportion of simulated samples in step 2 that lead to rejection. The significance level is the proportion of simulated samples in step 3 that lead to rejection.

Generating Random Distributions

Two methods are available in PASS to simulate random samples. The first method generates the random variates directly, one value at a time. The second method generates a large pool (over 10,000) of random values and then draws the random numbers from this pool. This second method can cut the running time of the simulation by 70%!

As mentioned above, the second method begins by generating a large pool of random numbers from the specified distributions. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is the maximum of twice the number of simulated samples desired and 10,000.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for: power or sample size (n). If you choose to solve for n, you must choose the type of power you want to solve for: any-pair power or all-pairs power. The value of the option Power will then represent this type of power.

Any-pair power is the probability of detecting at least one pair from among those that are actually different. All-pairs power is the probability of detecting all pairs that are actually different.

Note that the search for n may take several minutes because a separate simulation must be run for each trial value of n. You may find it quicker and more informative to solve for the Power for a range of sample sizes.

Simulations

This option specifies the number of iterations, M, used in the simulation. As the number of iterations is increased, the running time and accuracy are increased as well.

The precision of the simulated power estimates are calculated using the binomial distribution. Thus, confidence intervals may be constructed for various power values. The following table gives an estimate of the precision that is achieved for various simulation sizes when the power is either 0.50 or 0.95. The table values are interpreted as follows: a 95% confidence interval of the true power is given by the power reported by the simulation plus and minus the ‘Precision’ amount given in the table.

<table>
<thead>
<tr>
<th>Simulation Size M</th>
<th>Precision when Power = 0.50</th>
<th>Precision when Power = 0.95</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.100</td>
<td>0.044</td>
</tr>
<tr>
<td>500</td>
<td>0.045</td>
<td>0.019</td>
</tr>
<tr>
<td>1000</td>
<td>0.032</td>
<td>0.014</td>
</tr>
<tr>
<td>2000</td>
<td>0.022</td>
<td>0.010</td>
</tr>
<tr>
<td>5000</td>
<td>0.014</td>
<td>0.006</td>
</tr>
<tr>
<td>10000</td>
<td>0.010</td>
<td>0.004</td>
</tr>
<tr>
<td>50000</td>
<td>0.004</td>
<td>0.002</td>
</tr>
<tr>
<td>100000</td>
<td>0.003</td>
<td>0.001</td>
</tr>
</tbody>
</table>

Notice that a simulation size of 1000 gives a precision of plus or minus 0.01 when the true power is 0.95. Also note that as the simulation size is increased beyond 5000, there is only a small amount of additional accuracy achieved.
FWER (Alpha)

This option specifies one or more values of the family-wise error rate (FWER) which is the analog of alpha for multiple comparisons. FWER is the probability of falsely detecting (concluding that the means are different) at least one comparison for which the true means are the same. For independent tests, the relationship between the individual-comparison error rate (ICER) and FWER is given by the formulas

\[ FWER = 1 - (1 - ICER)^C \]

or

\[ ICER = 1 - (1 - FWER)^{1/C} \]

where '^' represents exponentiation (as in \(4^2 = 16\)) and C represents the number of comparisons. For example, if \(C = 5\) and \(FWER = 0.05\), then \(ICER = 0.0102\). Thus, the individual comparison tests must be conducted using a Type-1 error rate of 0.0102, which is much lower than the family-wise rate of 0.05.

The popular value for FWER remains at 0.05. However, if you have a large number of comparisons, you might decide that a larger value, such as 0.10, is appropriate.

Power

This option is only used when Find (Solve For) is set to n (All-Pairs) or n (Any-Pair).

Power is defined differently with multiple comparisons. Although many definitions are possible, two are adopted here. Any-pair power is the probability of detecting at least one pair of the means that are different. All-pairs power is the probability of detecting all pairs of means that are truly different. As the number of groups is increased, these power probabilities will decrease because more tests are being conducted.

Since this is a probability, the range is between 0 and 1. Most researchers would like to have the power at least at 0.8. However, this may require extremely large sample sizes when the number of tests is large.
**n (Sample Size Multiplier)**

This is the base, per group, sample size. One or more values separated by blanks or commas may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number by each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by \( m_1, m_2, m_3, ..., m_g \) and this value is represented by \( n \), the group sample sizes \( n_1, n_2, n_3, ..., n_g \) are calculated as follows:

\[
\begin{align*}
    n_1 &= [n(m_1)] \\
    n_2 &= [n(m_2)] \\
    n_3 &= [n(m_3)] \\
    \text{etc.}
\end{align*}
\]

where the operator, \([X]\) means the next integer after \( X \), e.g. \([3.1]=4\). This is required because sample sizes must be whole numbers.

For example, suppose there are three groups and the Group Sample Size Pattern is set to 1,2,3. If \( n \) is 5, the resulting sample sizes will be 5, 10, and 15. If \( n \) is 50, the resulting group sample sizes will be 50, 100, and 150. If \( n \) is set to 2,4,6,8,10; five sets of group sample sizes will be generated and an analysis run for each. These sets are:

\[
\begin{array}{ccc}
    2 & 4 & 6 \\
    4 & 8 & 12 \\
    6 & 12 & 18 \\
    8 & 16 & 24 \\
    10 & 20 & 30
\end{array}
\]

As a second example, suppose there are three groups and the Group Sample Size Pattern is 0.2,0.3,0.5. When the fractional Pattern values sum to one, \( n \) can be interpreted as the total sample size \( N \) of all groups and the Pattern values as the proportion of the total in each group.

If \( n \) is 10, the three group sample sizes would be 2, 3, and 5.

If \( n \) is 20, the three group sample sizes would be 4, 6, and 10.

If \( n \) is 12, the three group sample sizes would be

\[
\begin{align*}
    (0.2)12 &= 2.4 \text{ which is rounded up to the next whole integer, 3.} \\
    (0.3)12 &= 3.6 \text{ which is rounded up to the next whole integer, 4.} \\
    (0.5)12 &= 6.
\end{align*}
\]

Note that in this case, 3+4+6 does not equal \( n \) (which is 12). This can happen because of rounding.
**Group Sample Size Pattern**

The purpose of the group sample size pattern is to allow several groups with the same sample size to be generated without having to type each individually.

A set of positive, numeric values (one for each row of distributions) is entered here. Each item specified in this list applies to the whole row of distributions. For example, suppose the entry is 1 2 1 and Grps 1 = 3, Grps 2 = 1, Grps 3 = 2. The sample size pattern used would be 1 1 1 2 1 1.

The sample size of group $i$ is found by multiplying the $i$th number from this list by the value of $n$ and rounding up to the next whole number. The number of values must match the number of groups, $g$. When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

**Equal**

If all sample sizes are to be equal, enter *Equal* here and the desired sample size in $n$. A set of $g$ 1’s will be used. This will result in $n_1 = n_2 = \ldots = n_g = n$. That is, all sample sizes are equal to $n$.

**MC Procedure**

Specify which pair-wise multiple comparison procedure is to be reported from the simulations. The choices are:

- **Dunnett**
  
  This is the most popular and the most often recommended.

- **Kruskal-Wallis**
  
  This is recommended when a nonparametric procedure is wanted.

**Specifying Simulation Distributions**

These options specify the distributions to be used in the two simulations, one set per row. The first option specifies the number of groups represented by the two distributions that follow. The second option specifies the distribution to be used in simulating the null hypothesis to determine the significance level (alpha). The third option specifies the distribution to be used in simulating the alternative hypothesis to determine the power.

Note that group number one is the control group.

**Grps i (i = 1 to 9)**

This value specifies the number of groups specified by the H0 and H1 distribution statements to the right. Usually, you will enter ‘1’ to specify a single H0 and a single H1 distribution, or you will enter ‘0’ to indicate that the distributions specified on this line are to be ignored. This option lets you easily specify many identical distributions with a single phrase.

The total number of groups $g$ is equal to the sum of the values for the three rows of distributions shown under the Data1 tab and the six rows of distributions shown under the Data2 tab.

Note that each item specified in the *Group Sample Size Pattern* option applies to the whole row of entries here. For example, suppose the *Group Sample Size Pattern* was 1 2 1 and Grps 1 = 3, Grps 2 = 1, and Grps 3 = 2. The sample size pattern would be 1 1 1 2 1 1.

Note that since the first group is the control group, the value for Grps 1 is usually set to one.
Group i Distribution(s) | H0

This entry specifies the distribution of one or more groups under the null hypothesis, H0. The magnitude of the differences of the means of these distributions, which is often summarized as the standard deviation of the means, represents the magnitude of the mean differences specified under H0. Usually, the means are assumed to be equal under H0, so their standard deviation should be zero except for rounding.

These distributions are used in the simulations that estimate the actual significance level. They also specify the value of the mean under the null hypothesis, H0. Usually, these distributions will be identical. The parameters of each distribution are specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value $M_0$ is reserved for the value of the mean under the null hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean is entered first.

- Beta = A($M_0$, A, B, Minimum)
- Binomial = B($M_0$, N)
- Cauchy = C($M_0$, Scale)
- Constant = K(Value)
- Exponential = E($M_0$)
- F = F($M_0$, DF1)
- Gamma = G($M_0$, A)
- Multinomial = M(P1, P2, …, Pk)
- Normal = N($M_0$, SD)
- Poisson = P($M_0$)
- Student’s T = T($M_0$, D)
- Tukey’s Lambda = L($M_0$, S, Skewness, Elongation)
- Uniform = U($M_0$, Minimum)
- Weibull = W($M_0$, B)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

Finding the Value of the Mean of a Specified Distribution

Except for the multinomial distribution, the distributions have been parameterized in terms of their means since this is the parameter being tested. The mean of a distribution created as a linear combination of other distributions is found by applying the linear combination to the individual means. However, the mean of a distribution created by multiplying or dividing other distributions is not necessarily equal to applying the same function to the individual means. For example, the mean of $4N(4, 5) + 2N(5, 6)$ is $4*4 + 2*5 = 26$, but the mean of $4N(4, 5) * 2N(5, 6)$ is not exactly $4*4*2*5 = 160$ (although it is close).
Group i Distribution(s) | H1

Specify the distribution of this group under the alternative hypothesis, H1. This distribution is used in the simulation that determines the power. A fundamental quantity in a power analysis is the amount of variation among the group means. In fact, classical power analysis formulas, this variation is summarized as the standard deviation of the means.

The important point to realize is that you must pay particular attention to the values you give to the means of these distributions because they are fundamental to the interpretation of the simulation.

For convenience in specifying a range of values, the parameters of the distribution can be specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value of is reserved for the value of the mean under the alternative hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean, M1, is entered first.

- Beta=A(M1,A,B,Minimum)
- Binomial=B(M1,N)
- Cauchy=C(M1,Scale)
- Constant=K(Value)
- Exponential=E(M1)
- F=F(M1,DF1)
- Gamma=G(M1,A)
- Multinomial=M(P1,P2,\ldots,Pk)
- Normal=N(M1,SD)
- Poisson=P(M1)
- Student's T=T(M1,D)
- Tukey's Lambda=L(M1,S,Skewness,Elongation)
- Uniform=U(M1,Minimum)
- Weibull=W(M1,B)

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

M0 (Mean | H0)

These values are substituted for M0 in the distribution specifications given above. M0 is intended to be the value of the mean hypothesized by the null hypothesis, H0.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.

M1 (Mean | H1)

These values are substituted for M1 in the distribution specifications given above. Although it can be used wherever you want, M1 is intended to be the value of the mean hypothesized by the alternative hypothesis, H1.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.
Parameter Values (S, A, B, C)
Enter the numeric value(s) of the parameters listed above. These values are substituted for the corresponding letter in all four distribution specifications.

You can enter a list of values for each letter using the syntax 0 1 2 3 or 0 to 3 by 1.
You can also change the letter that is used as the name of this parameter using the pull-down menu to the side.

Minimum Difference
Specify the smallest difference between any two means that is to be detectable by the experiment. Pairs with mean differences smaller than this amount are to be considered equal.

Options Tab
The Options tab contains limits on the number of iterations and various options about individual tests.

Maximum Iterations
Specify the maximum number of iterations before the search for the sample size is aborted. When the maximum number of iterations is reached without convergence, the sample size is left blank. We recommend a value of at least 500.

Random Number Pool Size
This is the size of the pool of values from which the random samples will be drawn. Pools should be at least the maximum of 10,000 and twice the number of simulations. You can enter Automatic and an appropriate value will be calculated.
If you do not want to draw numbers from a pool, enter 0 here.

Reports Tab
The Reports tab contains settings about the format of the output.

Show Various Reports & Plots
These options let you specify whether you want to generate the standard reports and plots.

Show Inc’s & 95% C.I.
Checking this option causes an additional line to be printed showing a 95% confidence interval for both the power and actual alpha and half the width of the confidence interval (the increment).

Show Comparative Reports & Plots
These options let you specify whether you want to generate reports and plots that compare the test statistics that are available.
Example1 - Power at Various Sample Sizes

An experiment is being designed to compare the responses of three different treatments to a control. Previous studies have shown that the standard deviation within a group is 3.0. Researchers want to detect a shift in the mean of at least 2.0. To accomplish this, they set the mean of the control group to zero and the three treatment means to 2.0. They want to investigate sample sizes of 5, 10, 15, and 20 subjects per group.

Their primary analysis will be a set of Dunnett multiple comparison tests. They set the FWER to 0.05.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example1 template from the Template tab.

Summary of Simulations Report Definitions
H0: the null hypothesis that each treatment mean is equal to the control mean.
H1: the alternative hypothesis that at least one treatment mean differs from the control mean.
Pair: each comparison of a treatment mean and a control mean is a ‘pair’.
All-Pairs Power: the estimated probability of detecting all unequal pairs.
Any-Pairs Power: the estimated probability of detecting at least one unequal pair.
n: the average of the group sample sizes.
N: the combined sample size of all groups.
Family-Wise Error Rate (FWER): the probability of detecting at least one equal pair assuming H0.
Target FWER: the user-specified FWE.
Actual FWER: the FWER estimated by the alpha simulation.
Sm|H1: the standard deviation of the group means under H1.
SD|H1: the pooled, within-group standard deviation under H1.
Second Row: provides the precision and a confidence interval based on the size of the simulation for
Any-Pairs Power, All-Pairs Power, and FWER. The format is (Precision) [95% LCL and UCL Alpha].

Summary Statements
A one-way design with 3 treatment groups and one control group has an average group sample size
of 5.0 for a total sample size of 20. This design achieved an any-pair power of 0.187 and an
all-pair power of 0.0155 using the Dunnett’s Test procedure for comparing each treatment mean
with the control mean. The target family-wise error rate was 0.050 and the actual family-wise
error rate was 0.055. The average within group standard deviation assuming the alternative
distribution is 3.0. These results are based on 2000 Monte Carlo samples from the null
distributions: N(M0 S); N(M0 S); N(M0 S); and N(M0 S) and the alternative distributions: N(M0
S); N(M1 S); N(M1 S); and N(M1 S). Other parameters used in the simulation were: M0 = 0.0, M1 =
2.0, and S = 3.0.

This report shows the estimated any-pairs power, all-pairs power, and FWER for each scenario.
The second row shows three 95% confidence intervals in brackets: the first for the any-pairs
power, the second for the all-pairs power, and the third for the FWER. Half the width of each
confidence interval is given in parentheses as a fundamental measure of the precision of the simulation.
As the number of simulations is increased, the width of the confidence intervals will
decrease.

Any-Pairs Power
This is the probability of detecting any of the significant pairs. This value is estimated by the
simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are
shown on the line below this row. These values provide the precision of the estimated power.
All-Pairs Power
This is the probability of detecting all of the significant pairs. This value is estimated by the simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the estimated power.

Group Sample Size n
This is the average of the individual group sample sizes.

Total Sample Size N
This is the total sample size of the study.

S.D. of Means Sm|H1
This is the standard deviation of the hypothesized means of the alternative distributions. Under the null hypothesis, this value is zero. This value represents the magnitude of the difference among the means that is being tested. It is roughly equal to the average difference between the group means and the overall mean.

Note that the effect size is the ratio of Sm|H1 and SD|H1

S.D. of Data SD|H1
This is the within-group standard deviation calculated from samples from the alternative distributions.

Actual FWER
This is the value of FWER (family-wise error rate) estimated by the simulation using the H0 distributions. It should be compared with the Target FWER to determine if the test procedure is accurate.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the Actual FWER.

Target FWER
The target value of FWER.

M0
This is the value entered for M0, the group means under H0.

M1
This is the value entered for M1, the group means under H1.

S
This is the value entered for S, the standard deviation.

This report shows the results of the H0 simulation. This simulation uses the H0 settings for each group. Its main purpose is to provide an estimate of the FWER.

**No. of Equal Pairs**
Since under H0 all means are equal, this is the number of unique pairs of the groups. Thus, this is the number of treatment groups.

**Mean No. of Type-1 Errors**
This is the average number of type-1 errors (false detections) per set (family).

**Prop. Type-1 Errors**
This is the proportion of type-1 errors (false detections) among all tests that were conducted.

**Prop. (No. of Type-1 Errors > 0) FWER**
This is the proportion of the H0 simulations in which at least one type-1 error occurred. This is called the family-wise error rate.

**Target FWER**
This is the target value of FWER that was set by the user.

**Mean Pairs Alpha**
Alpha is the probability of rejecting H0 when H0 is true. It is a characteristic of an individual test. This is the average alpha value over all of the tests in the family.

**Min Pairs Alpha**
This is the minimum of all of the individual comparison alphas.

**Max Pairs Alpha**
This is the maximum of all of the individual comparison alphas.
### Error-Rate Summary for H1 Simulation

| Sim. No. | No. of Equal/Uneq. Pairs | Mean No. of False Pos. | Mean No. of False Neg. | Prop. Errors | Prop. Equal that were Detect. | Prop. Uneq. that were Undet. | (FDR) Prop. | 4        | 0/3                      | 0.00                   | 1.84                   | 0.613        | 0.000                       | 0.613                        | 0.000                             | 1.000                        | 0.162                | 0.623            | 0.388           | 0.380          | 0.392          |

This report shows the results of the H1 simulation. This simulation uses the H1 settings for each group. Its main purpose is to provide an estimate of the power.

**No. of Equal Pairs/Unequal Pairs**
The first value is the number of pairs for which the control mean and the treatment mean were equal under H1. The second value is the number of pairs for which the means were different under H1.

**Mean No. False Positives**
This is the average number of equal pairs that were declared as being unequal by the testing procedure. A *false positive* is a type-1 (alpha) error.

**Mean No. False Negatives**
This is the average number of unequal pairs that were not declared as being unequal by the testing procedure. A *false negative* is a type-2 (beta) error.

**Prop. Errors**
This is the proportion of type-1 and type-2 errors.

**Prop. Equal that were Detect.**
This is the proportion of the equal pairs in the H1 simulations that were declared as unequal.

**Prop. Uneq. that were Undet.**
This is the proportion of the unequal pairs in the H1 simulations that were not declared as being unequal.

**Prop. Detect. that were Equal (FDR)**
This is the proportion of detected pairs in the H1 simulations that were actually equal. This is often called the *false discovery rate*.

**Prop. Undet. that were Uneq.**
This is the proportion of undetected pairs in the H1 simulations that were actually unequal.

**All Uneq. Pairs Power**
This is the probability of detecting all of the pairs that were different in the H1 simulation.
Any Uneq. Pairs Power
This is the probability of detecting any of the pairs that were different in the H1 simulation.

Mean, Min, and Max Pairs Power
These items give the average, the minimum, and the maximum of the individual comparison powers from the H1 simulation.

This report shows details of each row of the previous reports.

Hypo. Type
This indicates which simulation is being reported on each row. H0 represents the null simulation and H1 represents the alternative simulation.
Groups
Each group in the simulation is assigned a number. This item shows the arbitrary group number that was assigned.

Group Labels
These are the labels that were used in the individual alpha-level reports. Note that the control group is labeled ‘Cntl’.

n/N
n is the average sample size of the groups. N is the total sample size across all groups.

Group Mean
These are the means of the individual groups as specified for the H0 and H1 simulations.

Ave. S.D.
This is the average standard deviation of all groups reported on each line. Note that it is calculated from the simulated data.

Simulation Model
This is the distribution that was used to simulate data for the groups reported on each line.

* Starred values are the powers of pairs that are unequal under H1.

This report shows the individual probabilities of rejecting each pair. When a pair was actually different, the value is the power of that test. These power values are starred.

The results shown on the upper-right section of each simulation report are from the H1 simulation. The results shown on the lower-left section of the report are from the H0 simulation.

**Plot Section**

These plots give a visual presentation of the all-pairs power values and the any-pair power values.
Example 2 - Comparative Results

Continuing with Example 1, the researchers want to study the characteristics of alternative multiple comparison procedures.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example 2 template from the Template tab.

These reports show the power and FWER of both of the multiple comparison procedures. In these simulations of groups from the normal distributions with equal variances, we see that the Dunnett’s procedure is the champion.
Example3 - Validation using Dunnett

Murkerjee, Robertson, and Wright (1987) page 909 present an example of a sample size calculation which was first discussed on page 1116 of Dunnett (1955). In this example there are five treatments and one control. The control mean and four of the treatment means are the same, while the fifth treatment mean is different.

The value of the within-group standard deviation is 1.0. Four treatment means and the control mean are -0.182574 and the fifth treatment mean is 0.912871. The FWER is 0.05 in the article, but this is for a one-sided test. Since PASS is finding the power for two-sided tests, we set FWER at 0.10. When the per-group sample size is 16, the all-pairs power is 0.80. When the per-group sample size is 21, the all-pairs power is 0.90. Note that since there is only one treatment that is different from the control, the all-pairs power is equal to the any-pairs power.

Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

For the first case when n = 16, PASS obtained a power of 0.795 which is very close to the value of 0.80 found by Muterjee et al. (1987). Indeed, 0.80 is within the confidence limits of 0.777 to 0.812. Similarly, the power for the second case when n = 21 is found as 0.894 which is very close to the article’s value of 0.90.
Chapter 590

Multiple Contrasts using Simulation

Introduction

This procedure uses simulation to analyze the power and significance level of two multiple-comparison procedures that perform two-sided hypothesis tests of contrasts of the group means. These are the Dunn-Bonferroni test and the Dunn-Welch test. For each scenario, two simulations are run: one estimates the significance level and the other estimates the power.

The term contrast refers to a user-defined comparison of the group means. The term multiple contrasts refers to a set of such comparisons. An additional restriction imposed is that the contrast coefficients sum to zero.

When several contrasts are tested, the interpretation of the results is more complex because of the problem of multiplicity. Multiplicity here refers to the fact that the probability of making at least one incorrect decision increases as the number of statistical tests increases. Methods for testing multiple contrasts have been developed to account for this multiplicity.

Error Rates

When dealing with several simultaneous statistical tests, both individual-wise and experiment-wise error rates should be considered.

1. Comparison-wise error rate. This is the probability of a type-I error (rejecting a true H0) for a particular test. In the case of the five-group design, there are ten possible comparison-wise error rates, one for each of the ten possible pairs. We will denote this error rate $\alpha_c$.

2. Experiment-wise (or family-wise) error rate. This is the probability of making one or more type-I errors in the set (family) of comparisons. We will denote this error rate $\alpha_f$.

The relationship between these two error rates when the tests are independent is given by

$$\alpha_f = 1 - (1 - \alpha_c)^C$$

where $C$ is the total number of contrasts. For example, if $\alpha_c$ is 0.05 and $C$ is 10, $\alpha_f$ is 0.401. There is about a 40% chance that at least one of the ten contrasts will be concluded to be non-zero when in fact they are not. When the tests are correlated, as they might be among a set of contrasts, the above formula provides an upper bound to the family-wise error rate.

The techniques described below provide control for $\alpha_f$ rather than $\alpha_c$. 
Technical Details

The One-Way Analysis of Variance Design

The discussion that follows is based on the common one-way analysis of variance design which may be summarized as follows. Suppose the responses $Y_{ij}$ in $k$ groups each follow a normal distribution with means $\mu_1, \mu_2, \ldots, \mu_k$ and unknown variance $\sigma^2$. Let $n_1, n_2, \ldots, n_k$ denote the number of subjects in each group. The control group is assumed to be group one.

The analysis of these responses is based on the sample means

$$\hat{\mu}_i = \bar{Y}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} Y_{ij}$$

and the pooled sample variance

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^{k} \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2}{\sum_{i=1}^{k} (n_i - 1)}$$

The $F$ test is the usual method of analysis of the data from such a design, testing whether all of the means are equal. However, a significant $F$ test does not indicate which of the groups are different, only that at least one is different. The analyst is left with the problem of determining which of the groups are different and by how much.

To determine the mean differences that are most importance, the researcher may specify a set of contrasts. These contrasts, called a priori, or, planned, contrasts should be specified before the experimental results are viewed.

The Dunn-Bonferroni procedure and the Dunn-Welch procedure have been developed to test these planned contrasts. The calculations associated with each of these tests are given below.

Contrasts

A contrast of the means is a stated difference among the means. The difference is constructed so that it represents a useful hypothesis. For example, suppose there are four groups, the first of which is a control group. It might be of interest to determine which treatments are statistically different from the control. That is, the differences $\mu_2 - \mu_1$, $\mu_3 - \mu_1$, and $\mu_4 - \mu_1$ would be tested to determine if they are non-zero.

Contrasts are often simple differences between two means. However, they may involve more than just two means. For example, suppose the first two groups receive one treatment and the second two groups receive another treatment. The contrast (difference) that would be tested is $(\mu_1 + \mu_2) - (\mu_3 + \mu_4)$. 
Every contrast can be represented by the list of contrast coefficients: the values by which the means are multiplied. Here are some examples of contrasts that might be of interest when the experiment involves four groups.

<table>
<thead>
<tr>
<th>Difference</th>
<th>Coefficients</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mu_2 - \mu_1$</td>
<td>-1, 1, 0, 0</td>

</tr>
<tr>
<td>$(\mu_1 + \mu_3) - (\mu_2 + \mu_4)$</td>
<td>3, -1, -1, -1</td>
</tr>
<tr>
<td>$(\mu_4 + \mu_1) - (\mu_2 + \mu_3)$</td>
<td>0, -1, -1, 2</td>
</tr>
</tbody>
</table>

Note that in each case, the coefficients sum to zero. This makes it possible to test whether the quantity is different from zero.

A lot is written about *orthogonal contrasts* which have the property that the sum of the products of corresponding coefficients is zero. For example, the sum of the products of the last two contrasts given above is $0(3) + (-1)(-1) + (-1)(-1) + (2)(-1) = 0 + 1 + 1 - 2 = 0$, so these two contrasts are orthogonal. However, the first two contrasts are not orthogonal since $(-1)(-1) + (1)(0) + (0)(1) + (0)(0) = 1 + 0 + 0 + 0 = 1$ (not zero). Orthogonal contrasts have nice properties when the sample sizes are equal. Unfortunately, they lose those properties when the group sample sizes are unequal or when the data are not normally distributed.

The procedures described in this chapter do not require that the contrasts be orthogonal. Instead, you should focus on defining a set of contrasts that answer the research questions of interest.

**Dunn-Bonferroni Test**

Dunn (1961) developed a procedure for simultaneously testing several contrasts. This method is also discussed in Kirk (1982) pages 106 to 109. The method consists of testing each contrast with Student’s $t$ distribution with degrees of freedom equal to $N-k$ with a Bonferroni adjustment of the alpha value. That is, the alpha value is divided by $C$, the number of contrasts simultaneously tested.

The test rejects $H_0$ if

$$\left|\frac{\sum_{i=1}^{k} C_i \bar{Y}_i}{\sqrt{\frac{S^2}{\sum_{i=1}^{k} \frac{C_i^2}{n_i}}}}\right| \geq t_{1-\alpha/(2C), N-k}$$

Note that this is a two-sided test of the hypothesis that $\sum_{i=1}^{k} C_i \mu_i = 0$ where $\sum_{i=1}^{k} C_i = 0$. 

Multiple Contrasts 590-3
Dunn-Welch Test

Dunn (1961) developed a procedure for simultaneously testing several contrasts. This method, using Welch’s (1947) modification for the unequal variances, is discussed in Kirk (1982) pages 100, 101, 106 - 109. The method consists of testing each contrast with Student’s $t$ distribution with degrees of freedom given below with a Bonferroni adjustment of the alpha value. That is, the alpha value is divided by $C$, the number of contrasts simultaneously tested.

The two-sided test statistic rejects $H_0$ if

\[
\left| \frac{\sum_{i=1}^{k} c_i \bar{Y}_i}{\sqrt{\sum_{i=1}^{k} \frac{c_i^2 \sigma_i^2}{n_i}}} \right| \geq t_{1 - \alpha/(2C), \nu'}
\]

where

\[
\nu' = \left( \sum_{i=1}^{k} \frac{c_i^2 \sigma_i^2}{n_i} \right)^2 \sum_{i=1}^{k} n_i^2 \left( n_i - 1 \right)
\]

Definition of Power for Multiple Contrasts

The notion of power is well-defined for individual tests. Power is the probability of rejecting a false null hypothesis. However, this definition does not extend directly when there are a number of simultaneous tests. The two definitions that we emphasize in PASS where recommended by Ramsey (1978). They are any-contrast power and all-contrasts power. Other design characteristics, such as average-contrast power and false-discovery rate, are important to consider. However, our review of the statistical literature resulted in our focus on these two definitions of power.

Any-Contrast Power

Any-contrast power is the probability of detecting at least one of the contrasts that are actually non-zero.

All-Contrasts Power

All-contrast power is the probability of detecting all of the contrasts that are actually non-zero.
Simulation Details

Computer simulation allows us to estimate the power and significance level that is actually achieved by a test procedure in situations that are not mathematically tractable. Computer simulation was once limited to mainframe computers. But, in recent years, as computer speeds have increased, simulation studies can be completed on desktop and laptop computers in a reasonable period of time.

The steps to a simulation study are

1. Specify how each test is to be carried out. This includes indicating how the test statistic is calculated and how the significance level is specified.

2. Generate random samples from the distributions specified by the alternative hypothesis. Calculate the test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the power of each test.

3. Generate random samples from the distributions specified by the null hypothesis. Calculate each test statistic from the simulated data and determine if the null hypothesis is accepted or rejected. The number rejected is used to calculate the significance level of each test.

4. Repeat steps 2 and 3 several thousand times, tabulating the number of times the simulated data leads to a rejection of the null hypothesis. The power is the proportion of simulated samples in step 2 that lead to rejection. The significance level is the proportion of simulated samples in step 3 that lead to rejection.

Generating Random Distributions

Two methods are available in PASS to simulate random samples. The first method generates the random variates directly, one value at a time. The second method generates a large pool (over 10,000) of random values and then draws the random numbers from this pool. This second method can cut the running time of the simulation by 70%!

As mentioned above, the second method begins by generating a large pool of random numbers from the specified distributions. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is the maximum of twice the number of simulated samples desired and 10,000.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for: power or sample size (n). If you choose to solve for n, you must choose the type of power you want to solve for: any-contrast power or all-contrasts power. The value of the option Power will then represent this type of power.

Any-contrast power is the probability of detecting at least one of the non-zero contrasts. All-contrast power is the probability of detecting all non-zero contrasts.

Note that the search for n may take several minutes because a separate simulation must be run for each trial value of n. You may find it quicker and more informative to solve for the Power for a range of sample sizes.

Simulations

This option specifies the number of iterations, $M$, used in the simulation. As the number of iterations is increased, the running time and accuracy are increased as well.

The precision of the simulated power estimates are calculated using the binomial distribution. Thus, confidence intervals may be constructed for various power values. The following table gives an estimate of the precision that is achieved for various simulation sizes when the power is either 0.50 or 0.95. The table values are interpreted as follows: a 95% confidence interval of the true power is given by the power reported by the simulation plus and minus the ‘Precision’ amount given in the table.

<table>
<thead>
<tr>
<th>Simulation Size M</th>
<th>Precision when Power = 0.50</th>
<th>Precision when Power = 0.95</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>0.100</td>
<td>0.044</td>
</tr>
<tr>
<td>500</td>
<td>0.045</td>
<td>0.019</td>
</tr>
<tr>
<td>1000</td>
<td>0.032</td>
<td>0.014</td>
</tr>
<tr>
<td>2000</td>
<td>0.022</td>
<td>0.010</td>
</tr>
<tr>
<td>5000</td>
<td>0.014</td>
<td>0.006</td>
</tr>
<tr>
<td>10000</td>
<td>0.010</td>
<td>0.004</td>
</tr>
<tr>
<td>50000</td>
<td>0.004</td>
<td>0.002</td>
</tr>
<tr>
<td>100000</td>
<td>0.003</td>
<td>0.001</td>
</tr>
</tbody>
</table>

Notice that a simulation size of 1000 gives a precision of plus or minus 0.01 when the true power is 0.95. Also note that as the simulation size is increased beyond 5000, there is only a small amount of additional accuracy achieved.
**FWER (Alpha)**

This option specifies one or more values of the *family-wise error rate* (FWER) which is the analog of alpha for multiple contrasts. FWER is the probability of falsely detecting (concluding that the means are different) at least one comparison for which the true means are the same. For independent tests, the relationship between the individual-comparison error rate (ICER) and FWER is given by the formulas

\[
FWER = 1 - (1 - ICER)^C
\]

or

\[
ICER = 1 - (1 - FWER)^{(1/C)}
\]

where "^" represents exponentiation (as in 4^2 = 16) and C represents the number of comparisons. For example, if C = 5 and FWER = 0.05, then ICER = 0.0102. Thus, the individual comparison tests must be conducted using a Type-1 error rate of 0.0102, which is much lower than the family-wise rate of 0.05.

The popular value for FWER remains at 0.05. However, if you have a large number of comparisons, you might decide that a larger value, such as 0.10, is appropriate.

**Power**

This option is only used when *Find (Solve For)* is set to n (All-Contrast) or n (Any-Contrast).

Power is defined differently with multiple contrasts. Although many definitions are possible, two are adopted here. *Any-contrast power* is the probability of detecting at least one non-zero contrast. *All-contrasts power* is the probability of detecting all non-zero contrasts. As the number of contrasts is increased, these power probabilities will decrease because more tests are being conducted.

Since this is a probability, the range is between 0 and 1. Most researchers would like to have the power at least at 0.8. However, this may require extremely large sample sizes when the number of tests is large.

**n (Sample Size Multiplier)**

This is the base, per group, sample size. One or more values separated by blanks or commas may be entered. A separate analysis is performed for each value listed here.

The group samples sizes are determined by multiplying this number by each of the Group Sample Size Pattern numbers. If the Group Sample Size Pattern numbers are represented by \(m1, m2, m3, ..., mg\) and this value is represented by \(n\), the group sample sizes \(n1, n2, n3, ...,ng\) are calculated as follows:

\[
n1=[n(m1)]
\]

\[
n2=[n(m2)]
\]

\[
n3=[n(m3)]
\]

etc.

where the operator, \([X]\) means the next integer after \(X\), e.g. \([3.1]=4\). This is required because sample sizes must be whole numbers.
For example, suppose there are three groups and the Group Sample Size Pattern is set to 1,2,3. If n is 5, the resulting sample sizes will be 5, 10, and 15. If n is 50, the resulting group sample sizes will be 50, 100, and 150. If n is set to 2,4,6,8,10; five sets of group sample sizes will be generated and an analysis run for each. These sets are:

2 4 6
4 8 12
6 12 18
8 16 24
10 20 30

As a second example, suppose there are three groups and the Group Sample Size Pattern is 0.2,0.3,0.5. When the fractional Pattern values sum to one, n can be interpreted as the total sample size N of all groups and the Pattern values as the proportion of the total in each group.

If n is 10, the three group sample sizes would be 2, 3, and 5.
If n is 20, the three group sample sizes would be 4, 6, and 10.
If n is 12, the three group sample sizes would be
\((0.2)12 = 2.4\) which is rounded up to the next whole integer, 3.
\((0.3)12 = 3.6\) which is rounded up to the next whole integer, 4.
\((0.5)12 = 6\).

Note that in this case, 3+4+6 does not equal n (which is 12). This can happen because of rounding.

**Group Sample Size Pattern**

The purpose of the group sample size pattern is to allow several groups with the same sample size to be generated without having to type each individually.

A set of positive, numeric values (one for each row of distributions) is entered here. Each item specified in this list applies to the whole row of distributions. For example, suppose the entry is 1 2 1 and Grps 1 = 3, Grps 2 = 1, Grps 3 = 2. The sample size pattern used would be 1 1 2 1 1.

The sample size of group \(i\) is found by multiplying the \(i\)th number from this list by the value of \(n\) and rounding up to the next whole number. The number of values must match the number of groups, \(g\). When too few numbers are entered, 1’s are added. When too many numbers are entered, the extras are ignored.

**Equal**

If all sample sizes are to be equal, enter Equal here and the desired sample size in \(n\). A set of \(g\) 1’s will be used. This will result in \(n1 = n2 = \ldots = ng = n\). That is, all sample sizes are equal to \(n\).

**MC Procedure**

Specify which multiple contrast procedure is to be reported from the simulations. The choices are

**Dunn-Bonferroni Test**

This is the most popular and most often recommended.

**Dunn-Welch**

This is recommended when the group variances are very different.
Specifying Simulation Distributions

These options specify the distributions to be used in the two simulations. The first option specifies the number of groups represented by the two distributions that follow. The second option specifies the distribution to be used in simulating the null hypothesis to determine the significance level (alpha). The third option specifies the distribution to be used in simulating the alternative hypothesis to determine the power.

**Grps i (i = 1 to 9)**

This value specifies the number of groups specified by the H0 and H1 distribution statements to the right. Usually, you will enter ‘1’ to specify a single H0 and a single H1 distribution, or you will enter ‘0’ to indicate that the distributions specified on this line are to be ignored. This option lets you easily specify many identical distributions with a single phrase.

The total number of groups $g$ is equal to the sum of the values for the three rows of distributions shown under the Data1 tab and the six rows of distributions shown under the Data2 tab.

Note that each item specified in the Group Sample Size Pattern option applies to the whole row of entries here. For example, suppose the Group Sample Size Pattern was $1 \ 2 \ 1$ and Grps 1 = 3, Grps 2 = 1, and Grps 3 = 2. The sample size pattern would be $1 \ 1 \ 2 \ 1 \ 1$.

**Group i Distribution(s) | H0**

This entry specifies the distribution of one or more groups under the null hypothesis, H0. The magnitude of the differences of the means of these distributions, which is often summarized as the standard deviation of the means, represents the magnitude of the mean differences specified under H0. Usually, the means are assumed to be equal under H0, so their standard deviation should be zero except for rounding.

These distributions are used in the simulations that estimate the actual significance level. They also specify the value of the mean under the null hypothesis, H0. Usually, these distributions will be identical. The parameters of each distribution are specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value $M0$ is reserved for the value of the mean under the null hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean is entered first.

- Beta=A(M0,A,B,Minimum)
- Binomial=B(M0,N)
- Cauchy=C(M0,Scale)
- Constant=K(Value)
- Exponential=E(M0)
- F=F(M0,DF1)
- Gamma=G(M0,A)
- Multinomial=M(P1,P2,...,Pk)
- Normal=N(M0,SD)
- Poisson=P(M0)
- Student's T=T(M0,D)
- Tukey's Lambda=L(M0,S,Skewness,Elongation)
- Uniform=U(M0,Minimum)
- Weibull=W(M0,B)
Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

**Finding the Value of the Mean of a Specified Distribution**

Except for the multinomial distribution, the distributions have been parameterized in terms of their means since this is the parameter being tested. The mean of a distribution created as a linear combination of other distributions is found by applying the linear combination to the individual means. However, the mean of a distribution created by multiplying or dividing other distributions is not necessarily equal to applying the same function to the individual means. For example, the mean of $4N(4, 5) + 2N(5, 6)$ is $4\times4 + 2\times5 = 26$, but the mean of $4N(4, 5) \times 2N(5, 6)$ is not exactly $4\times4\times2\times5 = 160$ (although it is close).

**Group i Distribution(s) | H1**

Specify the distribution of this group under the alternative hypothesis, $H_1$. This distribution is used in the simulation that determines the power. A fundamental quantity in a power analysis is the amount of variation among the group means. In fact, classical power analysis formulas, this variation is summarized as the standard deviation of the means.

The important point to realize is that you must pay particular attention to the values you give to the means of these distributions because they are fundamental to the interpretation of the simulation.

For convenience in specifying a range of values, the parameters of the distribution can be specified using numbers or letters. If letters are used, their values are specified in the boxes below. The value $M1$ is reserved for the value of the mean under the alternative hypothesis.

Following is a list of the distributions that are available and the syntax used to specify them. Note that, except for the multinomial, the distributions are parameterized so that the mean, $M1$, is entered first.

- Beta=$A(M1,A,B,Minimum)$
- Binomial=$B(M1,N)$
- Cauchy=$C(M1,Scale)$
- Constant=$K(Value)$
- Exponential=$E(M1)$
- $F=F(M1,DF1)$
- Gamma=$G(M1,A)$
- Multinomial=$M(P1,P2,…,Pk)$
- Normal=$N(M1,SD)$
- Poisson=$P(M1)$
- Student’s $T=T(M1,D)$
- Tukey’s Lambda=$L(M1,S,Skewness,Elongation)$
- Uniform=$U(M1,Minimum)$
- Weibull=$W(M1,B)$

Details of writing mixture distributions, combined distributions, and compound distributions are found in the chapter on Data Simulation and will not be repeated here.

**M0 (Mean | H0)**

These values are substituted for $M0$ in the distribution specifications given above. $M0$ is intended to be the value of the mean hypothesized by the null hypothesis, $H_0$.

You can enter a list of values using the syntax $0 1 2 3$ or $0 to 3 by 1$. 
**M1 (Mean | H1)**

These values are substituted for \( M1 \) in the distribution specifications given above. Although it can be used wherever you want, \( M1 \) is intended to be the value of the mean hypothesized by the alternative hypothesis, H1.

You can enter a list of values using the syntax 0 1 2 3 or 0 to 3 by 1.

**Parameter Values (S, A, B, C)**

Enter the numeric value(s) of the parameters listed above. These values are substituted for the corresponding letter in all four distribution specifications.

You can enter a list of values for each letter using the syntax 0 1 2 3 or 0 to 3 by 1.

You can also change the letter that is used as the name of this parameter using the pull-down menu to the side.

**Minimum Difference**

Specify the smallest difference between any two means that is to be detectable by the experiment. Contrasts with values smaller than this amount are to be considered equal.

**Contrasts Tab**

**Contrasts**

These options specify the contrasts. You can specify as many contrasts as are necessary, but a penalty is paid in terms of reduced power for each additional contrast. Thus, the number of contrasts should be limited to those that are most important to the study.

A contrast is a weighted average of the \( k \) (\( k \) = number of groups) group means in which the weights (coefficients) sum to zero. Each successive coefficient is applied to the corresponding group mean. For example, suppose \( k = 3 \) and the first group is a control group. Two contrasts that might be of interest are \(-1 1 0\) and \(-1 0 1\). These are interpreted as \((-1)\text{Mean1} + (1)\text{Mean2} + (0)\text{Mean3}\) and \((-1)\text{Mean1} + (0)\text{Mean2} + (1)\text{Mean3}\), respectively. Notice that the coefficients in each set sum to zero.

Several predefined sets of contrasts are available or you can specify your own. There is no set number of contrasts that must (or may) be specified, but fewer contrasts result in higher power and smaller required samples sizes.

Possible entries are given next.

**Individual Contrasts**

Enter a set of numbers, separated by blanks. One coefficient must be entered for each group with one set per box. Examples of valid contrasts are

-1 1  
-1 0 1  
0 1 -2 1  
-4 1 1 2
Each With First
This option generates $k-1$ contrasts appropriate for comparing each of the remaining groups with the first group. This might be used when the first group is a control group. If $k = 4$, the 3 contrasts are

-1 1 0 0
-1 0 1 0
-1 0 0 1

Each With Last
This option generates $k-1$ contrasts appropriate for comparing each of the first $k-1$ groups with the last group. This might be used when the last group is a control group. If $k = 4$, the 3 contrasts are

-1 0 0 1
0 -1 0 1
0 0 -1 1

Each With Next
This option generates $k-1$ contrasts appropriate for comparing each group with the next group. If $k = 4$, the 3 contrasts are

-1 1 0 0
0 -1 1 0
0 0 -1 1

Each With Remaining
Each group mean is compared with the average of those remaining to the right. Suppose $k=4$, the 3 contrasts are

-3 1 1 1
0 -2 1 1
0 0 -1 1

Each With All Others
Each group mean is compared with the average of the other groups. Suppose $k=4$, the 4 contrasts are

-3 1 1 1
1 -3 1 1
1 1 -3 1
1 1 1 -3

Progressive Split
The first groups are compared to the last groups. The dividing point moves from left to right. Suppose $k=5$, the 4 contrasts are

-4 1 1 1 1
-3 -3 2 2 2
-2 -2 -2 3 3
-1 -1 -1 -1 4.
Options Tab
The Options tab contains limits on the number of iterations and various options about individual tests.

Maximum Iterations
Specify the maximum number of iterations before the search for the sample size is aborted. When the maximum number of iterations is reached without convergence, the sample size is left blank. We recommend a value of at least 500.

Random Number Pool Size
This is the size of the pool of values from which the random samples will be drawn. Pools should be at least the maximum of 10,000 and twice the number of simulations. You can enter Automatic and an appropriate value will be calculated.

If you do not want to draw numbers from a pool, enter 0 here.

Reports Tab
The Reports tab contains settings about the format of the output.

Show Various Reports & Plots
These options let you specify whether you want to generate the standard reports and plots.

Show Inc’s & 95% C.I.
Checking this option causes an additional line to be printed showing a 95% confidence interval for both the power and actual alpha and half the width of the confidence interval (the increment).

Show Comparative Reports & Plots
These options let you specify whether you want to generate reports and plots that compare the test statistics that are available.
Example 1 - Power at Various Sample Sizes

A study is being planned to find the threshold level of a certain drug. Below this threshold level, the response has little change. Once the threshold level is reached, there is a sizeable jump in the mean response rate. Little change in the response occurs as the drug level is increased above the threshold. Scientists believe that the threshold level is between 3 and 7—their best estimate, based on previous studies, is 5. Previous studies have shown that the standard deviation within a group is 3.0.

In order to find the threshold, they design a study with five levels: 3.0, 4.0, 5.0, 6.0, and 7.0. Since there is no trend in the mean value (only a sudden shift) as the dose level is increased, they decide to test the following hypotheses:

<table>
<thead>
<tr>
<th>Difference</th>
<th>Coefficients</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mu_2 - \mu_1$</td>
<td>-1, 1, 0, 0, 0</td>
</tr>
<tr>
<td>$\mu_3 - \mu_2$</td>
<td>0, -1, 1, 0, 0</td>
</tr>
<tr>
<td>$\mu_4 - \mu_3$</td>
<td>0, 0, -1, 1, 0</td>
</tr>
<tr>
<td>$\mu_5 - \mu_4$</td>
<td>0, 0, 0, -1, 1</td>
</tr>
</tbody>
</table>

Notice that this set of hypotheses answers the question directly. An overall F-test would test the hypothesis that at least one mean is different, but it would not indicate which is different. The question might be settled by considering all possible pairs, but there are ten pairs, so ten hypothesis tests would have to be considered instead of only four—decreasing the power.

Researchers want to detect a shift in the mean as small as 2.0. Hence, they want to study the power when the means are 0.0, 0.0, 2.0, 2.0, 2.0. They want to investigate sample sizes of 10, 30, 50, and 70 subjects per group.

They have no reason to assume that the variance will change a great deal from group to group, so they decide to analyze the data using the Dunn-Bonferroni procedure. They set the FWER to 0.05. Note that, based on these means, only the second of the four contrasts will be significant, so the any-contrast power will be the same as the all-contrast power.
Setup
This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example1 template from the Template tab.

Summary of Simulations Report Definitions
H0: the null hypothesis that the contrast of the means is zero.
H1: the alternative hypothesis that the contrast of the means is not zero.
Cont.: abbreviates ‘Contrast’. Refers to a weighted average of the means whose weights sum to zero.
All-Cont. Power: the estimated probability of detecting all unequal contrasts.
Any-Cont. Power: the estimated probability of detecting at least one unequal contrast.
n: the average of the group sample sizes.
N: the combined sample size of all groups.
Family-Wise Error Rate (FWER): the probability of detecting at least one zero contrast assuming H0.
Target FWER: the user-specified FWE.
Actual FWER: the FWER estimated by the alpha simulation.
Sm|H1: the standard deviation of the group means under H1.
SD|H1: the pooled, within-group standard deviation under H1.

Summary Statements
A one-way design with 5 groups has an average group sample size of 10.0 for a total sample size of 50. This design achieved an any-contrast power of 0.136 and an all-contrast power of 0.136 using the Dunn-Bonferroni Test procedure for comparing each contrast of the group means with zero. The target family-wise error rate was 0.050 and the actual family-wise error rate was 0.048. The average within group standard deviation assuming the alternative distribution is 3.0. These results are based on 2000 Monte Carlo samples from the null distributions: N(M0 S); N(M0 S); N(M0 S); and N(M0 S); and the alternative distributions: N(M1 S); N(M1 S); and N(M1 S). Other parameters used in the simulation were: M0 = 0.0, M1 = 2.0, and S = 3.0.

This report shows that a group sample size of about 50 will be needed to achieve 80% power or about 70 for 90% power.

Any-Cont. Power
This is the probability of detecting any of the significant contrasts. This value is estimated by the simulation using the H1 distributions.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the estimated power.

All-Cont. Power
This is the probability of detecting all of the significant contrasts. This value is estimated by the simulation using the H1 distributions.
Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the estimated power.

**Group Sample Size n**
This is the average of the individual group sample sizes.

**Total Sample Size N**
This is the total sample size of the study.

**S.D. of Means Sm|H1**
This is the standard deviation of the hypothesized means of the alternative distributions. Under the null hypothesis this value is zero. It represents the magnitude of the difference among the means. It is roughly equal to the average difference between the group means and the overall mean.

Note that the effect size is the ratio of Sm|H1 and SD|H1.

**S.D. of Data SD|H1**
This is the within-group standard deviation calculated from samples from the alternative distributions.

**Actual FWER**
This is the value of FWER (family-wise error rate) estimated by the simulation using the H0 distributions. It should be compared with the Target FWER to determine if the test procedure is accurate.

Note that a precision value (half the width of its confidence interval) and a confidence interval are shown on the line below this row. These values provide the precision of the Actual FWER.

**Target FWER**
This is the target value of FWER that was set by the user.

**M0**
This is the value entered for M0, the group means under H0.

**M1**
This is the value entered for M1, the group means under H1.

**S**
This is the value entered for S, the standard deviation.

This report shows the results of the H0 simulation. This simulation uses the H0 settings for each group. Its main purpose is to provide an estimate of the FWER.

**No. of Zero Cont.**
Since under H0 all means are equal, this is the number of contrasts.

**Mean No. of Type-1 Errors**
This is the average number of type-1 errors (false detections) per set (family).

**Prop. Type-1 Errors**
This is the proportion of type-1 errors (false detections) among all tests that were conducted.

**Prop. (No. of Type-1 Errors>0) FWER**
This is the proportion of the H0 simulations in which at least one type-1 error occurred. This is called the family-wise error rate.

**Target FWER**
This is the target value of FWER that was set by the user.

**Mean Cont. Alpha**
Alpha is the probability of rejecting H0 when H0 is true. It is a characteristic of an individual test. This is the average individual alpha value over all of the contrasts.

**Min Cont. Alpha**
This is the minimum of all contrast alphas.

**Max Cont. Alpha**
This is the maximum of all contrast alphas.

### Notes

This report shows the results of the H1 simulation. This simulation uses the H1 settings for each group. Its main purpose is to provide an estimate of the power.

**No. of Zero/Non-0 Cont.**
The first value is the number of contrasts that were zero under H1. The second value is the number of contrasts that were non-zero under H1.

**Mean No. False Positives**
This is the average number of zero contrasts that were declared as being non-zero by the testing procedure. A *false positive* is a type-1 (alpha) error.

**Mean No. False Negatives**
This is the average number of non-zero contrasts that were not declared as being non-zero by the testing procedure. A *false negative* is a type-2 (beta) error.

**Prop. Errors**
This is the proportion of type-1 and type-2 errors.

**Prop. Equal that were Detect.**
This is the proportion of the zero contrasts in the H1 simulations that were declared as non-zero.

**Prop. Uneq. that were Undet.**
This is the proportion of non-zero contrasts in the H1 simulations that were not declared as being non-zero.

**Prop. Detect. that were Zero (FDR)**
This is the proportion of all detected contrasts in the H1 simulations that were actually zero. This is often called the *false discovery rate*.

**Prop. Undet. that were Non-0.**
This is the proportion of undetected contrasts in the H1 simulations that were actually non-zero.

**All Non-0 Cont. Power**
This is the probability of detecting all non-zero contrasts in the H1 simulation.

**Any Non-0 Cont. Power**
This is the probability of detecting any non-zero contrasts in the H1 simulation.
Mean, Min, and Max Cont. Power
These items give the average, the minimum, and the maximum of the contrast powers from the H1 simulation.

This report shows details of each row of the previous reports.

Hypo. Type
This indicates which simulation is being reported on each row. H0 represents the null simulation and H1 represents the alternative simulation.

Groups
Each group in the simulation is assigned a number. This item shows the arbitrary group number that was assigned.
**Group Labels**
These are the labels that were used in the individual alpha-level reports.

**n/N**
n is the average sample size of the groups. N is the total sample size across all groups.

**Group Mean**
These are the means of the individual groups as specified for the H0 and H1 simulations.

**Ave. S.D.**
This is the average standard deviation of all groups reported on each line. Note that it is calculated from the simulated data.

**Simulation Model**
This is the distribution that was used to simulate data for the groups reported on each line.

**List of Contrast Coefficients**

<table>

</tr>
</tbody>
</table>

The contrasts are shown down the rows. The groups are shown across the columns. The coefficients (weights) are shown as the body of the table.

This report shows values of the contrast coefficients so you can double-check that they are what was intended.

Alpha: probability of rejecting hypothesis that contrast is zero under alpha (H0) simulation.
Power: probability of rejecting hypothesis that contrast is zero under power (H1) simulation.

This report shows alpha and individual power for each contrast for each simulation that was run. In this example, only the second contrast was non-zero, so that is the only one which has large values for the power.

Plot Section

These plots give a visual presentation of the all-contrasts power values and the any-contrast power values.
**Example2 - Comparative Results**

Continuing with Example1, the researchers want to study the characteristics of alternative multiple contrast procedures.

**Setup**

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example2 template from the Template tab.

These reports show the power and FWER of both multiple contrast procedures. In these simulations of groups from the normal distributions with equal variances, there is little difference in the power of the two procedures.
Example 3 - Validation

We could not find an article that gives power values for this test, so we decided to validate the procedure by comparing its results to those of the one-way ANOVA procedure which allows a single contrast to be tested. Using the settings of Example 1 and using the contrast ‘0, -1, 1, 0, 0’, we obtained the following powers: 0.3085, 0.7274, 0.9131, and 0.9758.

Setup

This section presents the values of each of the parameters needed to run this example. You can enter these values yourself or load the Example3 template from the Template tab.

<td>3.0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In each case, the confidence interval includes the actual value. That is, 0.3085 is between 0.276 and 0.317, 0.7274 is between 0.721 and 0.760, 0.9131 is between 0.901 and 0.926, and 0.9758 is between 0.967 and 0.981. This validates the procedure.
Chapter 600

Hotelling’s T2

Introduction

This module calculates power for Hotelling’s one-group, and two-group, T-squared (T2) test statistics. Hotelling’s T2 is an extension of the univariate t-tests in which the number of response variables is greater than one. In the two-group case, these results may also be obtained using PASS’s MANOVA test.

Assumptions

The following assumptions are made when using Hotelling’s T2 to analyze one or two groups of data.

1. The response variables are continuous.
2. The residuals follow the multivariate normal probability distribution with mean zero and constant variance-covariance matrix.
3. The subjects are independent.

Technical Details

The formulas used to perform a Hotelling’s T2 power analysis provide exact answers if the above assumptions are met. These formulas can be found in many places. We use the results in Rencher (1998). We refer you to that reference for more details.

One-Group Case

In this case, a set of $N$ observations is available on $p$ response variables. We assume that all $N$ observations have the same multivariate normal distribution with mean vector $\mu$ and variance covariance matrix $\Sigma$ and that Hotelling’s T2 is used for testing the null hypothesis that $\mu = \mu_0$ versus the alternative that $\mu = \mu_A$ where at least one component of $\mu_A$ is different from the corresponding component of $\mu_0$. Usually, the vector $\mu_0$ is a vector of zeros.

The value of $T^2$ is computed using the formula

$$ T^2_{p,N-1} = N(\bar{y} - \mu_0)' S^{-1}(\bar{y} - \mu_0) $$

where $\bar{y}$ is the vector of sample means and $S$ is the sample variance-covariance matrix.
To calculate power we need the noncentrality parameter for this distribution. This noncentrality parameter is defined as follows

\[ \lambda = N(\mu_A - \mu_0)'\Sigma^{-1}(\mu_A - \mu_0) \]

\[ = NA^2 \]

where

\[ A = \sqrt{(\mu_A - \mu_0)'\Sigma^{-1}(\mu_A - \mu_0)} \]

We define \( A \) as effect size because it provides a expression for the magnitude of the standardized difference between the null and alternative means.

Using this noncentrality parameter, the power of the Hotelling’s T2 may be calculated for any value of the means and standard deviations. Since there is a simple relationship between the noncentral T2 and the noncentral \( F \), calculations are actually based on the noncentral \( F \) using the formula

\[ \beta = \Pr(F' < F'_{\alpha, df_1, df_2, \lambda}) \]

where

\[ df_1 = p \]
\[ df_2 = N - p \]

**Two-Group Case**

In this case, sets of \( N1 \) observations from group 1 and \( N2 \) observations from group 2 are available on \( p \) response variables. We assume that all observations have the multivariate normal distribution with common variance covariance matrix \( \Sigma \). The mean vectors of the two groups are assumed to be \( \mu_1 \) and \( \mu_2 \) under the alternative hypothesis. Under the null hypothesis, these mean vectors are assumed to be equal.

The value of \( T^2 \) is computed using the formula

\[ T^2_{p, N1+N2-2} = \frac{N1N2}{N1+N2} \left( \bar{y}_1 - \bar{y}_2 \right)'S^{-1}_{sp}(\bar{y}_1 - \bar{y}_2) \]

where \( \bar{y}_1 \) and \( \bar{y}_2 \) are the vectors sample mean vectors of the two groups and \( S_{sp} \) is the pooled sample variance-covariance matrix.
To calculate power we need the noncentrality parameter for this distribution. This noncentrality parameter is defined as follows

$$\lambda = \frac{N_1 N_2}{N_1 + N_2} \left( \mu_1 - \mu_2 \right)' \Sigma^{-1} \left( \mu_1 - \mu_2 \right)$$

$$= \frac{N_1 N_2}{N_1 + N_2} \Delta^2$$

where

$$\Delta = \sqrt{\left( \mu_1 - \mu_2 \right)' \Sigma^{-1} \left( \mu_1 - \mu_2 \right)}$$

We define $\Delta$ as *effect size* because it provides a expression for the magnitude of the standardized difference between the null and alternative means.

Using this noncentrality parameter, the power of the Hotelling’s $T^2$ may be calculated for any value of the means and standard deviations. Since there is a simple relationship between the noncentral $T^2$ and the noncentral $F$, calculations are actually based on the noncentral $F$ using the formula

$$\beta = \Pr(F' < \frac{F'_{\alpha, df_1, df_2, \lambda}}{df_2})$$

where

$$df_1 = p$$
$$df_2 = N_1 + N_2 - p - 1$$
Procedure Options

This section describes the options that are unique to this procedure. To find out more about using the other tabs, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains many of the options that you will be primarily concerned with.

Find (Solve For)

This option specifies the parameter to be solved for.

When you choose to solve for $N$ (one-group) or $N_1$ (two-group), the program searches for the lowest sample size that meets the alpha and beta criterion you have specified.

Groups

Specify whether the analysis is for one group or two groups. If ‘1’ is selected, $N_1$ is used as the sample size ($N$) and the values of $N_2$ and $R$ are ignored.

Response Variables

Enter the number of response (dependent or $Y$) variables. For a true multivariate test, this value will be greater than one.

The number of mean differences entered in the Mean Differences box or in the Means column must equal this value. If you read-in the covariance matrix from the spreadsheet, the number of columns specified must equal this value.

Mean Differences

Enter a list of values representing the mean differences under the alternative hypothesis. Under the null hypothesis, these values are all zero. The values entered here represent the differences that you want the experiment (study) to be able to detect.

Note that the number of values must match the number of Response Variables.

If you like, you can enter these values in a column on the spreadsheet. This column is specified using the ‘Means Column’ option. When that option is specified, any values entered here are ignored.

Means Column

Use this option to specify the spreadsheet column containing the hypothesized mean differences. The response variables are represented down the rows. The number of rows with data must equal the number of response variables. When this option is used, the ‘Mean Differences’ box is ignored.

You can obtain the spreadsheet by selecting ‘Window’, then ‘Data’, from the menus.

K (Means Multipliers)

These values are multiplied times the mean differences to give you various effect sizes. A separate power calculation is generated for each value of K. If you want to ignore this setting, enter ‘1’.
**Alpha (Significance Level)**

This option specifies the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis that all mean differences are zero. Since these are probabilities, alpha values must be between zero and one.

Historically, the value of 0.05 has been used for alpha. This value may be interpreted as meaning that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

**Beta (1 - Power)**

These options specify the probability of a type-II error (beta) for each factor and interaction. A type-II error occurs when you fail to reject the null hypothesis of equal effects when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is becoming more common. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify a beta value of 0.10, you are specifying the corresponding power value of 0.90.

**N1 (Sample Size Group 1)**

Enter a value (or range of values) for the sample size of group one. For the one-group case, this is the value of $N$. For the two-group case, this is the value of $N_1$.

You may enter a range of values such as ‘10 to 100 by 10’.

**N2 (Sample Size Group 2)**

In the two-group case, enter the value (or range of values) for the sample size of group two. In the one-group case, this value is ignored.

**Use R**

Enter ‘Use R’ if you want $N_2$ to be calculated using the formula: $N_2=[R \times N_1]$ where $R$ is the Sample Allocation Ratio and $[Y]$ is the first integer $\geq Y$. For example, if you want $N_1=N_2$, select ‘Use R’ here and set $R$ equal to one.

**Covariance Tab**

This tab specifies the covariance matrix.

**Specify Which Covariance Matrix Input Method to Use**

This option specifies which method will be used to define the covariance matrix.

**Standard Deviation and Correlation**

This option generates a covariance matrix based on the settings for the standard deviation (SD) and the pattern of correlations as specified in the Correlation Pattern and R options.
Covariance Matrix Variables

When this option is selected, the covariance matrix is read in from the columns of the spreadsheet. This is the most flexible method, but specifying a covariance matrix is tedious. You will usually only use this method when a specific covariance is given to you.

Note that the spreadsheet is shown by selecting the menus: ‘Window’ and then ‘Data’.

1) Specify Covariance Matrix Using SD’s and Correlations

The parameters in this section provide a flexible way to specify $\Sigma$, the covariance matrix. Because the covariance matrix is symmetric, it can be represented as

$$\Sigma = \begin{bmatrix}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1p} \\
\sigma_{12} & \sigma_{22} & \cdots & \sigma_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{1p} & \sigma_{2p} & \cdots & \sigma_{pp}
\end{bmatrix}$$

$$= \begin{bmatrix}
\sigma_1^2 & \sigma_1\sigma_2\rho_{12} & \cdots & \sigma_1\sigma_p\rho_{1p} \\
\sigma_1\sigma_2\rho_{12} & \sigma_2^2 & \cdots & \sigma_2\sigma_p\rho_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_1\sigma_p\rho_{1p} & \sigma_2\sigma_p\rho_{2p} & \cdots & \sigma_p^2
\end{bmatrix}$$

$$= \begin{bmatrix}
\sigma_1 & 0 & \cdots & 0 \\
0 & \sigma_2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sigma_p
\end{bmatrix} \begin{bmatrix}
1 & \rho_{12} & \cdots & \rho_{1p} \\
\rho_{12} & 1 & \cdots & \rho_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\rho_{1p} & \rho_{2p} & \cdots & 1
\end{bmatrix} \begin{bmatrix}
\sigma_1 & 0 & \cdots & 0 \\
0 & \sigma_2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sigma_p
\end{bmatrix}$$

where $p$ is the number of response variables.

Thus, the covariance matrix can be represented with complete generality by specifying the standard deviations $\sigma_1, \sigma_2, \cdots, \sigma_p$ and the correlation matrix

$$R = \begin{bmatrix}
1 & \rho_{12} & \cdots & \rho_{1p} \\
\rho_{12} & 1 & \cdots & \rho_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\rho_{1p} & \rho_{2p} & \cdots & 1
\end{bmatrix}.$$

SD (Common Standard Deviation)

This value is used to generate the covariance matrix. This option specifies a single standard deviation to be used for all response variables. The square of this value becomes the diagonal elements of the covariance matrix. Since this is a standard deviation, it must be greater than zero.

This option is only used when the first Covariance Matrix Input Method is selected.
Specify Correlation Pattern
This option specifies the pattern of the correlations in the variance-covariance matrix. Two options are available:

**Constant**
The value of $R$ is used as the constant correlation. For example, if $R = 0.6$ and $p = 6$, the correlation matrix would appear as

$$
R = \begin{bmatrix}
1 & 0.600 & 0.600 & 0.600 & 0.600 & 0.600 \\
0.600 & 1 & 0.600 & 0.600 & 0.600 & 0.600 \\
0.600 & 0.600 & 1 & 0.600 & 0.600 & 0.600 \\
0.600 & 0.600 & 0.600 & 1 & 0.600 & 0.600 \\
0.600 & 0.600 & 0.600 & 0.600 & 1 & 0.600 \\
0.600 & 0.600 & 0.600 & 0.600 & 0.600 & 1 \\
\end{bmatrix}
$$

**1st Order Autocorrelation**
The value of $R$ is used as the base autocorrelation in a first-order, serial correlation pattern. For example, $R = 0.6$ and $p = 6$, the correlation matrix would appear as

$$
R = \begin{bmatrix}
1 & 0.600 & 0.360 & 0.216 & 0.130 & 0.078 \\
0.600 & 1 & 0.600 & 0.360 & 0.216 & 0.130 \\
0.360 & 0.600 & 1 & 0.600 & 0.360 & 0.216 \\
0.216 & 0.360 & 0.600 & 1 & 0.600 & 0.360 \\
0.130 & 0.216 & 0.360 & 0.600 & 1 & 0.600 \\
0.078 & 0.130 & 0.216 & 0.360 & 0.600 & 1 \\
\end{bmatrix}
$$

This pattern is often chosen as the most realistic when little is known about the correlation pattern and the responses variables are measured across time.

**R (Correlation)**
Specify a correlation to be used in calculating the off-diagonal elements of the covariance matrix. Since this is a correlation, it must be between -1 and 1. This option is only used when the first Covariance Matrix Input Method is selected.

**2) Specify Covariance Matrix using Spreadsheet Columns**
This option instructs the program to read the covariance matrix from the spreadsheet.

**Spreadsheet Columns Containing the Covariance Matrix**
This option designates the columns on the current spreadsheet holding the covariance matrix. It is used when the ‘Specify Which Covariance Matrix Input Method to Use’ option is set to Covariance Matrix Variables. The number of columns and number of rows must match the number of response variable at which the subjects are measured.
Reports Tab
This tab specifies which reports and graphs are displayed as well as their format.

Numeric Results
Specify whether to display the numeric report.

Means Matrix
Specify whether to display the mean differences.

Covariance Matrix
Specify whether to display the covariance matrix.

Show Definitions
Specify whether to display a list of definitions for each value in the numeric report.

Show Plot
Specify whether to display this plot.

Report Prob. Dec’s - K Dec’s
Specify the number of decimal places on these items in the reports.

Summary Statement Rows
The program will output a text statement summarizing the results for each scenario. This option specifies the number of scenarios (rows) from the Numerical Report that will have a summary statement displayed. Select 0 to omit the summary statement.
Example 1 - Power in the One-Group Case and Validation

Rencher (1998) page 106 presents an example of power calculations for the one-group case in which the mean differences are both 1.88 and the covariance matrix is

\[
\Sigma = \begin{bmatrix}
56.78 & 11.98 \\
11.98 & 29.28 \\
\end{bmatrix}
\]

When \( N \) is 25 and the significance level is 0.05, Rencher calculated the power to be 0.3397.

To allow for a nice chart, we will calculate the power for several samples sizes and for \( K \) equal 1.0 and 1.5.

For your convenience, the covariance matrix has been stored in a spreadsheet called RENCHER2.S0. You must open that spreadsheet to run this example.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions
Power is the probability of rejecting a false null hypothesis. Note that Power = 1 - Beta.
N is the sample size, the number of subjects in the experiment or study.
K is a constant by which all means are multiplied.
Alpha is the probability of rejecting a true null hypothesis.
Beta is the probability of accepting a false null hypothesis. Note that Beta = 1 - Power.
Effect Size is a standardized version of T2 under the alternative hypothesis.
DF1 is the first degrees of freedom of T2. It is the number of response variables.
DF2 is the second degrees of freedom of T2.

Summary Statements
A sample size of 5 achieves 7% power to detect an effect size of 0.38 which represents the differences between the null and alternative means of the 2 response variables, adjusted by the variance-covariance matrix. The one-sample Hotelling’s T-squared test statistic is used with a significance level of 0.0500.

This report gives the power for each value of N and K. Notice that the power for K = 1 and N = 25 is 0.3379. This is slightly different than the 0.3397 obtained by interpolation by Rencher.

Means Matrix

<table>

This report shows the variance-covariance matrix that was read in from the spreadsheet or generated by the settings of on the Covariance tab. The standard deviations are given on the diagonal and the correlations are given off the diagonal.

Chart Section

This chart shows the relationship between power and $N$ for each value of $K$. 
Example2 - Power in the Two-Group Case and Validation

Rencher (1998) pages 107-108 presents an example of power calculations for the two-group case in which the mean differences and covariance matrix are

\[
\mu_1 - \mu_2 = \begin{bmatrix} 3 \\ -2 \\ 3 \end{bmatrix}, \quad \Sigma = \begin{bmatrix} 6 & -3 & 3 \\ -3 & 5 & -6 \\ 3 & -6 & 9 \end{bmatrix}
\]

When \( N_1 = N_2 = 10, 12, 14, 16 \) and the significance level is 0.05, Rencher calculated the power to be 0.6438, 0.7520, 0.8329, 0.8936, respectively.

For your convenience, the mean differences and covariance matrix have been stored in a spreadsheet called RENCHER2.S0. You must open that spreadsheet to run this example.

**Setup**

You can enter these values yourself or load the Example2 template from the Template tab.

Note that the power values obtained here are very close to those obtained by Rencher. We feel that our results are more accurate since Rencher’s results were obtained by interpolation from Tang’s tables.
600-14 Hotelling's T2
Chapter 605

MANOVA

Introduction

This module calculates power for multivariate analysis of variance (MANOVA) designs having up to three factors. It computes power for three MANOVA test statistics: Wilks’ lambda, Pillai-Bartlett trace, and Hotelling-Lawley trace.

MANOVA is an extension of common analysis of variance (ANOVA). In ANOVA, differences among various group means on a single-response variable are studied. In MANOVA, the number of response variables is increased to two or more. The hypothesis concerns a comparison of vectors of group means. The multivariate extension of the $F$-test is not completely direct. Instead, several test statistics are available. The actual distributions of these statistics are difficult to calculate, so we rely on approximations based on the $F$-distribution.

Assumptions

The following assumptions are made when using MANOVA to analyze a factorial experimental design.

1. The response variables are continuous.
2. The residuals follow the multivariate normal probability distribution with mean zero and constant variance-covariance matrix.
3. The subjects are independent.
Technical Details

General Linear Multivariate Model

This section provides the technical details of the MANOVA designs that can be analyzed by PASS. The approximate power calculations outlined in Muller, LaVange, Ramey, and Ramey (1992) are used. Using their notation, for \( N \) subjects, the usual general linear multivariate model is

\[
Y_{N \times p} = XM_{N \times q \times p} + R_{N \times p}
\]

where each row of the residual matrix \( R \) is distributed as a multivariate normal

\[

row_k(R) \sim N_p(0, \Sigma)
\]

Note that \( p \) is the number of response variables and \( q \) is the number of design variables, \( Y \) is the matrix of responses, \( X \) is the design matrix, \( M \) is the matrix of regression parameters (means), and \( R \) is the matrix of residuals.

Hypotheses about various sets of regression parameters are tested using

\[
H_0: \Theta = \Theta_0
\]

\[
CM_{a \times q \times p} = \Theta
\]

where \( C \) is an orthonormal contrast matrix and \( \Theta_0 \) is a matrix of hypothesized values, usually zeros. Note that \( C \) defines contrasts among the factor levels. Tests of the various main effects and interactions may be constructed with suitable choices of \( C \). These tests are based on

\[
\hat{M} = (X'X)^{-1}X'Y
\]

\[
\hat{\Theta} = CM
\]

\[
H_{p \times p} = (\hat{\Theta} - \Theta_0)' \left[ C(X'X)^{-1}C \right]^{-1}(\hat{\Theta} - \Theta_0)
\]

\[
E = \hat{\Sigma} \cdot (N - r)
\]

\[
T = H + E
\]

where \( r \) is the rank of \( X \).
Wilks’ Lambda Approximate F Test

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using Wilks’ likelihood ratio statistic $W$. This statistic is computed using

$$W = |ET^{-1}|$$

An $F$ approximation to the distribution of $W$ is given by

$$F_{df_1, df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2}$$

where

$$\lambda = df_1 F_{df_1, df_2}$$
$$\eta = 1 - W^{\lambda / g}$$
$$df'1 = ap$$
$$df'2 = g\left[ (N - r) - (p - a + 1) / 2 \right] - (ap - 2) / 2$$
$$g = \left( \frac{a^2 p^2 - 4}{a^2 + p^2 - 5} \right)^{1/2}$$
**Pillai-Bartlett Trace Approximate F Test**

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using the Pillai-Bartlett Trace. This statistic is computed using

$$T_{PB} = \text{tr}(HT^{-1})$$

A noncentral $F$ approximation to the distribution of $T_{PB}$ is given by

$$F_{df_1, df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2}$$

where

$$\lambda = df_1 F_{df_1, df_2}$$

$$\eta = \frac{T_{PB}}{s}$$

$$s = \min(a, p)$$

$$df_1 = ap$$

$$df_2 = s[(N - r) - p + s]$$
Hotelling-Lawley Trace Approximate F Test

The hypothesis $H_0: \Theta = \Theta_0$ may be tested using the Hotelling-Lawley Trace. This statistic is computed using

$$T_{HL} = \text{tr}(HE^{-1})$$

An $F$ approximation to the distribution of $T_{HL}$ is given by

$$F_{df_1,df_2} = \frac{\eta/df_1}{(1-\eta)/df_2}$$

where

$$\lambda = df_1F_{df_1,df_2}$$

$$\eta = s\frac{T_{HL}}{1+T_{HL}/s}$$

$$s = \min(a,p)$$

$$df_1 = ap$$

$$df_2 = s[(N-r)-p+s]$$

M (Mean) Matrix

In the general linear multivariate model presented above, $M$ represents a matrix of regression coefficients. Although other structures and interpretations of $M$ are possible, in this module we assume that the elements of $M$ are the cell means. The rows of $M$ represent the factor categories and the columns of $M$ represent the response variables. (Note that this is just the opposite of the orientation used when entering $M$ into the spreadsheet.)

The $q$ rows of $M$ represent the $q$ groups into which the subjects can be classified. For example, if a design includes three factors with 2, 3, and 4 categories, the matrix $M$ would have $2 \times 3 \times 4 = 24$ rows. That is, $q = 24$.

Consider now an example in which $q = 3$ and $p = 4$. That is, there are three groups into which subjects can be placed. Each subject has four made. The matrix $M$ would appear as follows.

$$M = \begin{bmatrix}
\mu_{11} & \mu_{12} & \mu_{13} & \mu_{14} \\
\mu_{21} & \mu_{22} & \mu_{23} & \mu_{24} \\
\mu_{31} & \mu_{32} & \mu_{33} & \mu_{34}
\end{bmatrix}$$

For example, the element $\mu_{12}$ is the mean of the second response of subjects in the first group. To calculate the power of this design, you would need to specify appropriate values of all twelve means.
C Matrix - Contrasts
The C matrix is comprised of contrasts that are applied to the rows of M. You do not have to specify these contrasts. They are generated for you. You should understand that a different C matrix is generated for each term in the model.

Generating the C Matrix when there are Multiple Between Factors.
Generating the C matrix when there is more than one factor is more difficult. We use the method of O’Brien and Kaiser (1985) which we briefly summarize here.

Step 1. Write a complete set of contrasts suitable for testing each factor separately. For example, if you have three factors with 2, 3, and 4 categories, you might use

\[
\tilde{C}_b = \begin{bmatrix}
\frac{-1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\
\end{bmatrix}, \quad \tilde{C}_b = \begin{bmatrix}
\frac{-2}{\sqrt{6}} & \frac{1}{\sqrt{6}} & \frac{1}{\sqrt{6}} \\
\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\
0 & 0 & 0
\end{bmatrix}, \quad \text{and} \quad \tilde{C}_b = \begin{bmatrix}
\frac{-3}{\sqrt{12}} & \frac{1}{\sqrt{12}} & \frac{1}{\sqrt{12}} & \frac{1}{\sqrt{12}} \\
\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\
0 & \frac{-2}{\sqrt{6}} & \frac{1}{\sqrt{6}} & \frac{1}{\sqrt{6}} \\
0 & 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{bmatrix}.
\]

Step 2. Define appropriate \( J_k \) matrices corresponding to each factor. These matrices comprised of one row and k columns whose equal element is chosen so that the sum of its elements squared is one. In this example, we use

\[
J_2 = \begin{bmatrix}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\
\end{bmatrix}, \quad J_3 = \begin{bmatrix}
\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\
\end{bmatrix}, \quad J_4 = \begin{bmatrix}
\frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} \\
\end{bmatrix}
\]
Step 3. Create the appropriate contrast matrix using a direct (Kronecker) product of either the $\tilde{C}_{bi}$ matrix if the factor is included in the term or the $J_i$ matrix when the factor is not in the term. Remember that the direct product is formed by multiplying each element of the second matrix by all members of the first matrix. Here is an example

\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix} \otimes 
\begin{bmatrix}
1 & 0 & -1 \\
0 & 2 & 0 \\
-1 & 0 & 3
\end{bmatrix}
\]

\[
= \begin{bmatrix}
1 & 2 & 0 & 0 & -1 & -2 \\
3 & 4 & 0 & 0 & -3 & -4 \\
0 & 0 & 2 & 4 & 0 & 0 \\
0 & 0 & 6 & 8 & 0 & 0 \\
-1 & -2 & 0 & 0 & 3 & 6 \\
-3 & -4 & 0 & 0 & 9 & 12
\end{bmatrix}
\]

As an example, we will compute the $C$ matrix suitable for testing factor $B_2$

\[C_{B2} = J_2 \otimes \tilde{C}_{B2} \otimes J_4\]

Expanding the direct product results in

\[C_{B2} = \begin{bmatrix}
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\
\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\
0 & 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{bmatrix} \otimes 
\begin{bmatrix}
\frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} \\
\frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} \\
\frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} \\
\frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}} & \frac{1}{\sqrt{4}}
\end{bmatrix}
\]

\[= \begin{bmatrix}
\frac{-2}{\sqrt{48}} & \frac{1}{\sqrt{48}} & \frac{1}{\sqrt{48}} & \frac{-1}{\sqrt{48}} \\
\frac{-2}{\sqrt{48}} & \frac{-1}{\sqrt{48}} & \frac{-1}{\sqrt{48}} & \frac{1}{\sqrt{48}} \\
\frac{-2}{\sqrt{48}} & \frac{-1}{\sqrt{48}} & \frac{-1}{\sqrt{48}} & \frac{-1}{\sqrt{48}} \\
\frac{0}{\sqrt{48}} & \frac{0}{\sqrt{48}} & \frac{0}{\sqrt{48}} & \frac{0}{\sqrt{48}}
\end{bmatrix}
\]

Similarly, the $C$ matrix suitable for testing interaction $B2B3$ is

\[C_{B2B3} = J_2 \otimes \tilde{C}_{B2} \otimes \tilde{C}_{B3}\]

We leave the expansion of this matrix PASS, but we think you have the idea.
Power Calculations

To calculate statistical power, we must determine distribution of the test statistic under the alternative hypothesis which specifies a different value for the regression parameter matrix $B$. The distribution theory in this case has not been worked out, so approximations must be used. We use the approximations given by Mueller and Barton (1989) and Muller, LaVange, Ramey, and Ramey (1992). These approximations state that under the alternative hypothesis, $F_U$ is distributed as a noncentral $F$ random variable with degrees of freedom and noncentrality shown above. The calculation of the power of a particular test may be summarized as follows.

1. Specify values of $X$, $M$, $\Sigma$, $C$, and $\Theta_0$.

2. Determine the critical value using $F_{\text{crit}} = FINV(1 - \alpha, df_1, df_2)$, where $FINV(\cdot)$ is the inverse of the central $F$ distribution and $\alpha$ is the significance level.

3. Compute the noncentrality parameter $\lambda$.

4. Compute the power as

$$Power = 1 - NCFPROB(F_{\text{crit}}, df_1, df_2, \lambda)$$

where $NCFPROB(\cdot)$ is the noncentral $F$ distribution.
Procedure Options

This section describes the options that are unique to this procedure. To find out more about using the other tabs, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains many of the options that you will be primarily concerned with.

Find (Solve For)

This option specifies the parameter to be solved for. If you choose to solve for \(n\) (sample size), you must also specify which test statistic you want to use.

When you choose to solve for \(n\), the program searches for the lowest sample size that meets the alpha and beta criterion you have specified for each of the terms. If you do not want a term to be used in the search, set its alpha and beta values to 0.99.

Also, when the ‘= n’s’ box is not checked, the search is made using unequal group sample sizes. The relative proportion of the sample in each group is set by the values of \(n\) given in the Subjects Per Group box. For example, if your design has three groups and you entered ‘1 1 2’ in the Subjects Per Group box, the search will only consider designs in which the size of the last group is twice the rest. That is, it will consider ‘2 2 4’, ‘3 3 6’, ‘4 4 8’, etc.

Note: no plots are generated when you solve for \(n\).

\(n\) (Subjects Per Group)

Specify one or more values for the number of subjects per group. The total sample size is the sum of the individual group sizes across all groups.

You can specify a list like ‘2 4 6’. The items in the list may be separated with commas or blanks. The interpretation of the list depends on the =n's check box. When the =n's box is checked, a separate analysis is calculated for each value of \(n\). When the =n's box is not checked, PASS uses the \(n\)’s as the actual group sizes. In this case, the number of items entered must match the number of groups in the design.

When you choose to solve for \(n\) and the = n’s box is not checked, the search is made using unequal group sample sizes. The relative proportion of the sample in each group is set by the values of \(n\) given in this box. For example, if your design has three groups and you enter ‘1 1 2’ here, the search will only consider designs in which the size of the last group is twice the rest. That is, it will consider ‘2 2 4’, ‘3 3 6’, ‘4 4 8’, etc.

= n’s

This option controls whether the number of subjects per group is to be equal for all groups or not. When checked, the number of subjects per group is equal for all groups. A list of values such as ‘5 10 15’ represents three designs: one with five per group, one with ten per group, and one with fifteen per group.

When this option is not checked, the \(n\)’s are assumed to be unequal. A list of values represents the size of the individual groups. For example, ‘5 10 15’ represents a single, three-group design with five in the first group, ten in the second group, and fifteen in the third group.
Means Matrix
Use this option to specify spreadsheet columns containing a hypothesized means matrix that is used to specify the alternative hypothesis. You can obtain the spreadsheet by selecting ‘Window’, then ‘Data’, from the menus.

The factors are represented across the columns of the spreadsheet and the response variables are represented down the rows. The number of columns specified must equal the number of groups. The number of rows with data in these columns must equal the number of response variables. For example, suppose you are designing an experiment that is to have two factors (A and B) and two response variables (Y1 and Y2). Suppose each of the factors has two levels. The four columns of the spreadsheet would represent

The two rows of the spreadsheet would represent
Y1
Y2

K (Means Multipliers)
These values are multiplied times the means matrix to give you various effect sizes. A separate power calculation is generated for each value of K. These values become the horizontal axis in the second power chart. If you want to ignore this setting, enter ‘1’.

Labels
Specify a label for this factor. Although we suggest that only a single letter be used, the label can consist of several letters. When several letters are used, the labels for the interactions may be extra long and confusing. Of course, you must be careful not to use the same label for two factors.

One of the easiest sets of labels is to use A, B, and C for the factors.

Levels
Specify the number of levels (categories) in this factor. Typical values are from 2 to 8. Set this to a blank (or 0) to ignore the factor in the design.

Alpha
These options specify the probability of a type-I error (alpha) for each factor and interaction. A type-I error occurs when you reject the null hypothesis of zero effects when in fact they are zero. Since they are probabilities, alpha values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This value may be interpreted as meaning that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

You can specify different alpha values for different terms. For example, although you have three terms in an experiment, you might be mainly interested in only one of them. Hence, you could increase the alpha level of the tests of the other terms and thereby increase their power. Also, you may want to increase the alpha level of the interaction terms, as these will often have poor power otherwise.
**Beta**

These options specify the probability of a type-II error (beta) for each factor and interaction. A type-II error occurs when you fail to reject the null hypothesis of equal effects when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is becoming more common. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify a beta value of 0.10, you are specifying the corresponding power value of 0.90.

**Response Variables**

Enter the number of response variables in your design. For a true MANOVA, this value must be greater than one. The number of rows in the means matrix must equal this value. If you specify a covariance matrix, the number of columns specified must equal this value.

**Covariance Tab**

This tab specifies the covariance matrix.

**Specify Which Covariance Matrix Input Method to Use**

This option specifies which method will be used to define the covariance matrix.

**Standard Deviation and Correlation**

This option generates a covariance matrix based on the settings for the standard deviation (SD) and the pattern of correlations as specified in the Correlation Pattern and R options.

**Covariance Matrix Variables**

When this option is selected, the covariance matrix is read in from the columns of the spreadsheet. This is the most flexible method, but specifying a covariance matrix is tedious. You will usually only use this method when a specific covariance is given to you.

Note that the spreadsheet is shown by selecting the menus: ‘Window’ and then ‘Data’.
1) Specify Covariance Matrix Using SD’s and Correlations

The parameters in this section provide a flexible way to specify \( \Sigma \), the covariance matrix. Because the covariance matrix is symmetric, it can be represented as

\[
\Sigma = \begin{bmatrix}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1p} \\
\sigma_{12} & \sigma_{22} & \cdots & \sigma_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{1p} & \sigma_{2p} & \cdots & \sigma_{pp}
\end{bmatrix}
\]

where \( p \) is the number of response variables.

Thus, the covariance matrix can be represented with complete generality by specifying the standard deviations \( \sigma_1, \sigma_2, \ldots, \sigma_p \) and the correlation matrix

\[
R = \begin{bmatrix}
1 & \rho_{12} & \cdots & \rho_{1p} \\
\rho_{12} & 1 & \cdots & \rho_{2p} \\
\vdots & \vdots & \ddots & \vdots \\
\rho_{1p} & \rho_{2p} & \cdots & 1
\end{bmatrix}
\]

SD (Standard Deviation)

This value is used to generate the covariance matrix. This option specifies a standard deviation to be used for all response variables. The square of this value becomes the diagonal elements of the covariance matrix. Since this is a standard deviation, it must be greater than zero.

This option is only used when the first Covariance Matrix Input Method is selected.
Specify Correlation Pattern

This option specifies the pattern of the correlations in the variance-covariance matrix. Two options are available:

**Constant**

The value of R is used as the constant correlation. For example, if $R = 0.6$ and $p = 6$, the correlation matrix would appear as

$$R = \begin{bmatrix}
1 & 0.600 & 0.600 & 0.600 & 0.600 & 0.600 \\
0.600 & 1 & 0.600 & 0.600 & 0.600 & 0.600 \\
0.600 & 0.600 & 1 & 0.600 & 0.600 & 0.600 \\
0.600 & 0.600 & 0.600 & 1 & 0.600 & 0.600 \\
0.600 & 0.600 & 0.600 & 0.600 & 1 & 0.600 \\
0.600 & 0.600 & 0.600 & 0.600 & 0.600 & 1 \\
\end{bmatrix}$$

**1st Order Autocorrelation**

The value of R is used as the base autocorrelation in a first-order, serial correlation pattern. For example, $R = 0.6$ and $p = 6$, the correlation matrix would appear as

$$R = \begin{bmatrix}
1 & 0.600 & 0.360 & 0.216 & 0.130 & 0.078 \\
0.600 & 1 & 0.600 & 0.360 & 0.216 & 0.130 \\
0.360 & 0.600 & 1 & 0.600 & 0.360 & 0.216 \\
0.216 & 0.360 & 0.600 & 1 & 0.600 & 0.360 \\
0.130 & 0.216 & 0.360 & 0.600 & 1 & 0.600 \\
0.078 & 0.130 & 0.216 & 0.360 & 0.600 & 1 \\
\end{bmatrix}$$

This pattern is often chosen as the most realistic when little is known about the correlation pattern and the responses variables are measured across time.

**R (Correlation)**

Specify a correlation to be used in calculating the off-diagonal elements of the covariance matrix. Since this is a correlation, it must be between -1 and 1. This option is only used when the first Covariance Matrix Input Method is selected.

**2) Specify Covariance Matrix using Spreadsheet Columns**

This option instructs the program to read the covariance matrix from the spreadsheet.
Spreadsheet Columns Containing the Covariance Matrix

This option designates the columns on the current spreadsheet holding the covariance matrix. It is used when the ‘Specify Which Covariance Matrix Input Method to Use’ option is set to Covariance Matrix Variables. The number of columns and number of rows must match the number of response variable at which the subjects are measured.

Reports Tab

This tab specifies which reports and graphs are displayed as well as their format.

Skip Line After

The names of the terms can be too long to fit in the space provided. If the name contains more characters than this, the rest of the output is placed on a separate line. Enter ‘1’ when you want every term’s results printed on two lines. Enter ‘100’ when you want every variable’s results printed on one line.

Test in Summary Statement

Indicate the test that is to be reported on in the Summary Statements.

Maximum Term-Order Reported

Indicate the maximum order of terms to be reported on. Occasionally, higher-order interactions are of little interest and so they may be omitted. For example, enter a ‘2’ to limit output to individual factors and two-way interactions.
Example 1 - Determining Power

Researchers are planning a study of the impact of a drug. They want to evaluate the differences in heart rate and blood pressure among three age groups: 20-40, 41-60, and over 60. They want to be able to detect a 10% change in heart rate and in blood pressure among the age groups. They plan to analyze the data using Wilks’ lambda.

Previous studies have found an average heart rate of 93 with a standard deviation of 4 and an average blood pressure of 130 with a standard deviation of 5. The correlation between the two responses will be set at 0.7.

From a heart rate of 93, a 10% reduction gives 84. They want to be able to detect age-group heart-rate means that range from 93 to 84. From a blood pressure of 130, a 10% reduction gives 117. The want to be able to detect age-group blood-pressure means that range from 130 to 117. Hence, the means matrix that they will use is

C1  C2  C3
93  88  84
130 124 117

Based on the standard deviation settings that they chose to use, the covariance matrix will be

C4  C5
16   14
14   25

In order to understand the relationship between power and sample size, they decide to calculate power values for sample sizes between 2 and 12, using a 0.05 significance level.

For your convenience, the Means Matrix and Covariance Matrix have been stored in a spreadsheet called PASSMANOVA1.S0. You can enter the above values yourself or you can open that spreadsheet.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

### Summary Statements

A MANOVA design with 1 factor and 2 response variables has 3 groups with 2 subjects each for a total of 6 subjects. This design achieves 7% power to test factor A if a Wilks' Lambda Approximate F Test is used with a 5% significance level.

This report gives the power for each value of \( n \) and \( K \). It is useful when you want to compare the powers of the terms in the design at a specific sample size.

In this example, for \( K = 1 \), the design goal of 0.95 power is achieved for \( n = 8 \).

The definitions of each of the columns of the report are as follows.

#### Test

This column identifies the test statistic. Since the power depends on the test statistic, you should make sure that this is the test statistic that you will use in your analysis.

#### Power

This is the computed power for the term.

#### n

The value of \( n \) is the number of subjects per group.

#### N

The value of \( N \) is the total number of subjects in the study.

#### Multiply Means By

This is the value of the means multiplier, \( K \).

#### Test Statistic

This is the value of the test statistic computed at the hypothesized values. The name of the statistic is identified in the Test column. Possible values are Wilks' lambda, Pillai-Bartlett trace, or Hotelling-Lawley trace. The actual formulas used were given earlier in the Technical Details section.
**Approx. F Statistic**

This is the value of the $F$ statistic that is used to compute the probability levels. This value is calculated using the hypothesized values. The actual formulas used were given earlier in the Technical Details section.

**DF1|DF2**

These are the numerator and denominator degrees of freedom of the approximating $F$ distribution.

**Alpha**

Alpha is the significance level of the test.

**Beta**

Beta is the probability of failing to reject the null hypothesis when the alternative hypothesis is true.

### Means Matrix

<table>
<thead>
<tr>
<th>Name</th>
<th>A1</th>
<th>A2</th>
<th>A3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y1</td>
<td>93.00</td>
<td>88.00</td>
<td>84.00</td>
</tr>
<tr>
<td>Y2</td>
<td>130.00</td>
<td>124.00</td>
<td>117.00</td>
</tr>
</tbody>
</table>

This report shows the means matrix that was read in. It may be used to get an impression of the magnitude of the difference among the means that is being studied. When a Means Multiplier, $K$, is used, each value of $K$ is multiplied times each value of this matrix.

### Variance-Covariance Matrix Section

<table>
<thead>
<tr>
<th>Response</th>
<th>Y1</th>
<th>Y2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y1</td>
<td>4.00</td>
<td>0.70</td>
</tr>
<tr>
<td>Y2</td>
<td>0.70</td>
<td>5.00</td>
</tr>
</tbody>
</table>

This report shows the variance-covariance matrix that was read in from the spreadsheet or generated by the settings of on the Covariance tab. The standard deviations are given on the diagonal and the correlations are given off the diagonal.
These charts show the relationship between power and $n$ for each value of $K$. Note that high-order interactions may be omitted from the plot by reducing the Max Term-Order Plotted option on the Plot Setup tab.

These charts show the relationship between power and $K$ for each value of $n$. Remember that $K$ is the mean multiplier. It changes the effect size.
Example 2 - Validation

In this example, we will set $p = 2$, $q = 3$, $\alpha = 0.05$, and $n = 4$. The mean and covariance matrices are

$$M = \begin{bmatrix} 1 & 1 \\ 2 & 1 \\ 3 & 2 \end{bmatrix} \quad \Sigma = \begin{bmatrix} 4 & 1 \\ 1 & 4 \end{bmatrix}$$

The contrast matrix $C$ is

$$C = \begin{bmatrix} -2 & \sqrt{6} & \sqrt{6} \\ -1 & -1 & \sqrt{2} \\ 0 & \sqrt{2} & \sqrt{2} \end{bmatrix}$$

The $X'X$ matrix is

$$X'X = \begin{bmatrix} 4 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 4 \end{bmatrix}$$

The matrix $\Theta$ is

$$\Theta = CM = \begin{bmatrix} 3 & 1 \\ \sqrt{6} & \sqrt{6} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix}$$

The matrix $H$ is

$$H = (\hat{\Theta} - \Theta_0)' [C(X'X)^{-1} C]' (\hat{\Theta} - \Theta_0) = \begin{bmatrix} 8 & 4 \\ 4 & 8 / 3 \end{bmatrix}$$

The matrix $E$ is

$$E = \hat{\Sigma} \cdot (N - r) = \begin{bmatrix} 36 & 9 \\ 9 & 36 \end{bmatrix}$$

The matrix $T$ is

$$T = H + E = \begin{bmatrix} 44 & 13 \\ 13 & 38 \frac{2}{3} \end{bmatrix}$$
Using these matrices, we can calculate the values of the test statistics. We will only calculate the results for Wilks’ lambda. We have

\[
W = \det(ET^{-1}) \\
= 0.79290842 \\
a = q - 1 \\
= 2 \\
g = \left( \frac{a^2 p^2 - 4}{a^2 + p^2 - 5} \right)^{\frac{1}{2}} \\
= \left( \frac{2^2 2^2 - 4}{2^2 + 2^2 - 5} \right)^{\frac{1}{2}} \\
= 2 \\
\eta = 1 - W^{1/g} \\
= 1 - \sqrt{0.79290842} \\
= 0.10954595 \\
df_1 = ap \\
= 4 \\
df_2 = g\left[(N - r) - (p - a + 1)/2 \right] - (ap - 2)/2 \\
= 2\left[(12 - 3) - (2 - 2 + 1)/2 \right] - (4 - 2)/2 \\
= 16 \\
F_{df_1, df_2} = \frac{\eta / df_1}{(1 - \eta) / df_2} \\
= \frac{0.10954595 / 4}{(1 - 0.10954595) / 16} \\
= 0.49209030 \\
\lambda = df_1 F_{df_1, df_2} \\
= 4(0.49209030) \\
= 1.96836120
\]

For an \(F\) with 4 and 16 degrees of freedom, the 5% critical value is 3.0069172799. Finally, compute the power using a noncentral \(F\) with 4 and 16 degrees of freedom and noncentrality parameter

\[
Power = \Pr(f > F|df_1 = 4, df_2 = 16, \lambda = 1.96836120) \\
= 0.1370631884
\]
In order to run this example in **PASS**, the values of the means and the covariance matrix (given above) must be entered on a spreadsheet. We have loaded these values into the database called PASSMANOVA2. Either enter the values yourself, or load the PASSMANOVA2 database which should be in the Data directory. The instructions below assume that the means are in columns C1-C3, while the covariance matrix is in columns C4-C5.

**Setup**

You can enter these values yourself or load the Example2 template from the Template tab.

As you can see, the power computed here matches the results we computed manually.
Chapter 630

Data Simulator

Introduction

Because of mathematical intractability, it is often necessary to investigate the properties of a statistical procedure using simulation (or Monte Carlo) techniques. In power analysis, simulation refers to the process of generating several thousand random samples that follow a particular distribution, calculating the test statistic from each sample, and tabulating the distribution of these test statistics so that the significance level and power of the procedure may be investigated. This module creates a histogram of a specified distribution as well as a numerical summary of simulated data. By studying the histogram and the numerical summary, you can determine if the distribution has the characteristics you desire. The distribution formula can then be used in procedures that use simulation, such as the new t-test procedures. Below are examples of two distributions that were generated with this procedure.
Technical Details

A random variable’s probability distribution specifies its probability over its range of values. Examples of common continuous probability distributions are the normal and uniform distributions. Unfortunately, experimental data often do not follow these common distributions, so other distributions have been proposed. One of the easiest ways to create distributions with desired characteristics is to combine simple distributions. For example, outliers may be added to a distribution by mixing it with data from a distribution with a much larger variance. Thus, to simulate normally distributed data with 5% outliers, we could generate 95% of the sample from a normal distribution with mean 100 and standard deviation 4 and then generate 5% of the sample from a normal distribution with mean 100 and standard deviation 16. Using the standard notation for the normal distribution, the composite distribution of the new random variable \( Y \) could be written as

\[
Y \sim \delta(0 \leq X < 0.95)N(100,4) + \delta(0.95 \leq X \leq 1.00)N(100,16)
\]

where \( X \) is a uniform random variable between 0 and 1, \( \delta(z) \) is 1 or 0 depending on whether \( z \) is true or false, \( N(100,4) \) is a normally distributed random variable with mean 100 and standard deviation 4, and \( N(100,16) \) is a normally distributed random variable with mean 100 and standard deviation 16. The resulting distribution is shown below. Notice how the tails extend in both directions.

The procedure for generating a random variable, \( Y \), with the mixture distribution described above is

1. Generate a uniform random number, \( X \).

2. If \( X \) is less than 0.95, \( Y \) is created by generating a random number from the \( N(100,4) \) distribution.

3. If \( X \) is greater than or equal to 0.95, \( Y \) is created by generating a random number from the \( N(100,16) \) distribution.

Note that only one uniform random number and one normal random number are generated for any particular random realization from the mixture distribution.
In general, the formula for a mixture random variable, $Y$, which is to be generated from two or more random variables defined by their distribution function $F_i(Z_i)$ is given by

$$Y \sim \sum_{i=1}^{k} \delta(a_i \leq X < a_{i+1})F_i(Z_i), \quad a_i = 0 < a_2 < \cdots < a_{k+1} = 1$$

Note that the $a_i$’s are chosen so that weighting requirements are met. Also note that only one uniform random number and one other random number actually need to be generated for a particular value. The $F_i(Z_i)$’s may be any of the distributions which are listed below.

Since the test statistics which will be simulated are used to test hypotheses about one or more means, it will be convenient to parameterize the distributions in terms of their means.

**Beta Distribution**

The beta distribution is given by the density function

$$f(x) = \frac{\Gamma(A+B)}{\Gamma(A)\Gamma(B)} \left( \frac{x-C}{D-C} \right)^{A-1} \left( 1 - \frac{x-C}{D-C} \right)^{B-1}, \quad A, B > 0, C \leq x \leq D$$

where $A$ and $B$ are shape parameters, $C$ is the minimum, and $D$ is the maximum. In statistical theory, $C$ and $D$ are usually zero and one, respectively, but the more general formulation used here is more convenient for simulation work. In this program module, a beta random variable is specified as $A(M, A, B, C)$, where $M$ is the mean which is

$$E(X) = M = (D - C) \left[ \frac{A}{A + B} \right] + C$$

The parameter $D$ is obtained from $M, A, B$, and $C$ using the relationship

$$D = \frac{(M - C)(A + B)}{A} + C.$$ 

The beta density can take a number of shapes depending on the values of $A$ and $B$:

1. When $A<1$ and $B<1$ the density is U-shaped.
2. When $0 < A < 1 \leq B$ the density is J-shaped.

3. When $A=1$ and $B>1$ the density is bounded and decreases monotonically to 0.

4. When $A=1$ and $B=1$ the density is the uniform density.

5. When $A>1$ and $B>1$ the density is unimodal.

Beta random variates are generated using Cheng’s rejection algorithm as given on page 438 of Devroye (1986).
**Binomial Distribution**

The binomial distribution is given by the function

\[
\Pr(X = x) = \binom{n}{x} \pi^x (1 - \pi)^{n-x}, \quad x = 0, 1, 2, \ldots, n
\]

In this program module, the binomial is specified as \(B(M, n)\), where \(M\) is the mean which is equal to \(n\pi\) and \(n\) is the number of trials. The probability of a positive response, \(\pi\), is not entered directly, but is obtained using the relationship \(\pi = M / n\). For this reason, \(0 < M < n\).

Binomial random variates are generated using the inverse CDF method. That is, a uniform random variate is generated, and then the CDF of the binomial distribution is scanned to determine which value of \(X\) is associated with that probability.

**Cauchy Distribution**

The Cauchy distribution is given by the density function

\[
f(x) = \left[ S\pi \left(1 + \left(\frac{x - M}{S}\right)^2\right)\right]^{-1}, \quad S > 0
\]

Although the Cauchy distribution does not possess a mean and standard deviation, \(M\) and \(S\) are treated as such. Cauchy random numbers are generated using the algorithm given in Johnson, Kotz, and Balakrishnan (1994), page 327.

In this program module, the Cauchy is specified as \(C(M, S)\), where \(M\) is a location parameter (median), and \(S\) is a scale parameter.
Constant Distribution

The constant distribution occurs when a random variable can only take a single value, $X$. The constant distribution is specified as $K(X)$, where $X$ is the value.

Data with a Many Zero Values

Sometimes data follow a specific distribution in which there is a large proportion of zeros. This can happen when data are counts or monetary amounts. Suppose you want to generate exponentially distributed data with an extra number of zeros. You could use the following simulation model:

$K(0)[2] ; E(5)[9]$

The exponential distribution alone was used to generate the histogram below on the left. The histogram below on the right was simulated by adding extra zeros to the exponential data.
**Exponential Distribution**

The exponential distribution is given by the density function

\[ f(x) = \frac{1}{M} e^{-\frac{x}{M}}, \quad x > 0 \]

In this program module, the exponential is specified as \( E(M) \), where \( M \) is the mean.

Random variates from the exponential distribution are generated using the expression

\[ -M \ln(U), \quad \text{where } U \text{ is a uniform random variate.} \]
F Distribution

Snedecor’s $F$ distribution is the distribution of the ratio of two independent chi-square variates. The degrees of freedom of the numerator chi-square variate is $A$, while that of the denominator chi-square is $D$. The $F$ distribution is specified as $F(M, A)$, where $M$ is the mean and $A$ is the degrees of freedom of the numerator chi-square. The value of $M$ is related to the denominator chi-square degrees of freedom using the relationship $M = D/(D-2)$.

$F$ variates are generated by first generating a symmetric beta variate, $B(A/2,D/2)$, and transforming it into an $F$ variate using the relationship

$$F_{A,D} = \frac{BD}{A - BA}$$

Below is a histogram for data generated from an $F$ distribution with a mean of 1.1 and $A = 6$. 

![Histogram of F Distribution](image-url)
Gamma Distribution

The three parameter gamma distribution is given by the density function

\[ f(x) = \frac{(x)^{A-1}}{B^A \Gamma(A)} e^{-\frac{x}{B}}, \quad x > 0, \ A > 0, \ B > 0 \]

where \(A\) is a shape parameter and \(B\) is a scale parameter. In this program module, the gamma is specified as \(G(M, A)\), where \(M\) is the mean, given by \(M = AB\). The parameter \(B\) may be obtained using the relationship \(B = M/A\).

Gamma variates are generated using the exponential distribution when \(A = 1\), Best’s XG algorithm given in Devroye (1986), page 410, when \(A > 1\), and Vaduva’s algorithm given in Devroye (1986), page 415, when \(A < 1\).
Multinomial Distribution

The multinomial distribution occurs when a random variable has only a few discrete values such as 1, 2, 3, 4, and 5. The multinomial distribution is specified as $M(P_1, P_2, \ldots, P_k)$, where $P_i$ is the probability of that the integer $i$ occurs. Note that the values start at one, not zero.

For example, suppose you want to simulate a distribution which has 50% 3’s and 1’s, 2’s, 4’s, and 5’s all with equal percentages. You would enter $M(1 1 4 1 1)$.

As a second example, suppose you wanted to have a equal percentage of 1’s, 3’s, and 7’s, and none of the other percentages. You would enter $M(1 0 1 0 0 0 1)$.

Likert-Scale Data

Likert-scale data are common in surveys and questionnaires. To generate data from a five-point Likert-scale distribution, you could use the following simulation model:

$M(6 1 2 1 5)$

Note that the weights are relative—they do not have to sum to one. The program will make the appropriate weighting adjustments so that they do sum to one.

The above expression generated the following histogram.
Normal Distribution
The normal distribution is given by the density function
\[ f(x) = \phi\left(\frac{x - \mu}{\sigma}\right), \quad -\infty \leq x \leq \infty \]
where \( \phi(z) \) is the usual standard normal density. The normal distribution is specified as \( N(M, S) \), where \( M \) is the mean and \( S \) is the standard deviation.
The normal distribution is generated using the Marsaglia and Bray algorithm as given in Devroye (1986), page 390.

Poisson Distribution
The Poisson distribution is given by the function
\[ \Pr(X = x) = \frac{e^{-M}M^x}{x!}, \quad x = 0, 1, 2, \ldots, M > 0 \]
In this program module, the Poisson is specified as \( P(M) \), where \( M \) is the mean.
Poisson random variates are generated using the inverse CDF method. That is, a uniform random variate is generated and then the CDF of the Poisson distribution is scanned to determine which value of \( X \) is associated with that probability.
Student’s T Distribution

Student’s $T$ distribution is the distribution of the ratio of a unit normal variate and the square root of an independent chi-square variate. The degrees of freedom of the chi-square variate are the degrees of freedom of the $T$ distribution. The $T$ is specified as $T(M, A)$, where $M$ is the mean and $A$ is the degrees of freedom. The central $T$ distribution generated in this program has a mean of zero, so, to obtain a mean of $M$, $M$ is added to every data value.

$T$ variates are generated by first generating a symmetric beta variate, $B(A/2, A/2)$, with mean equal to 0.5. This beta variate is then transformed into a $T$ variate using the relationship

$$T = \sqrt{A} \frac{X - 0.5}{\sqrt{X(1 - X)}}$$

Here is a histogram for data generated from a $T$ distribution with mean 0 and 5 degrees of freedom.
Tukey’s Lambda Distribution

Hoainglin (1985) presents a discussion of a distribution developed by John Tukey for allowing the detailed specification of skewness and kurtosis in a simulation study. This distribution is extended in the work of Karian and Dudewicz (2000). Tukey’s idea was to reshape the normal distribution using functions that change the skewness and/or kurtosis. This is accomplished by multiplying a normal random variable by a skewness function and/or a kurtosis function. The general form of the transformation is

\[ X = A + B \left( G_g(z) H_h(z) z \right) \]

where \( z \) has the standard normal density. The skewness function Tukey proposed is

\[ G_g(z) = e^{gz} - 1 \]

The range of \( g \) is typically -1 to 1. The value of \( G_0(z) = 1 \). The kurtosis function Tukey proposed is

\[ H_h(z) = e^{hz^2/2} \]

The range of \( h \) is also -1 to 1.

Hence, if both \( g \) and \( h \) are set to zero, the variable \( X \) follows the normal distribution with mean \( A \) and standard deviation \( B \). As \( g \) is increased toward 1, the distribution is increasingly skewed to the right. As \( g \) is decreased towards -1, the distribution is increasingly skewed to the left. As \( h \) is increased toward 1, the data are stretched out so that more extreme values are probable. As \( h \) is decreased toward -1, the data are concentrated around the center—resulting in a beta-type distribution.

The mean of this distribution is given by

\[ M = A + B \left( e^{g^{1/2}(1-h)} \right) - 1 \]

which may be easily solved for \( A \).

Tukey’s lambda is specified in the program as \( L(M, B, g, h) \) where \( M \) is the mean, \( B \) is a scale factor (when \( g=h=0, B \) is the standard deviation), \( g \) is the amount of skewness, and \( h \) is the amount of kurtosis.

Random variates are generated from this distribution by generating a random normal variate and then applying the skewness and kurtosis modifications. Here are some examples as \( g \) is varied from 0 to 0.4 to 0.6. Notice how the amount of skewness is gradually increased. Similar results are achieved when \( h \) is varied from 0 to 0.5.
Uniform Distribution
The uniform distribution is given by the density function

\[ f(x) = \frac{1}{B - A}, \quad A \leq x \leq B \]

In this program module, the uniform is specified as \( U(M, A) \), where \( M \) is the mean which is equal to \((A+B)/2\) and \( A \) is the minimum of \( x \). The parameter \( B \) is obtained using the relationship \( B = 2M - A \).

Uniform random numbers are generated using Makoto Matsumoto’s Mersenne Twister uniform random number generator which has a cycle length greater than \( \) (that’s a one followed by 6000 zeros).
Weibull Distribution

The Weibull distribution is indexed by a shape parameter, $B$, and a scale parameter, $C$. The Weibull density function is written as

$$f(x|B,C) = \frac{B}{C}\left(\frac{z}{C}\right)^{B-1} e^{-\left(\frac{z}{C}\right)^B}, \quad B > 0, \ C > 0, \ x > 0.$$  

Shape Parameter - $B$

The shape parameter controls the overall shape of the density function. Typically, this value ranges between 0.5 and 8.0. One of the reasons for the popularity of the Weibull distribution is that it includes other useful distributions as special cases or close approximations. For example, if

- $B = 1$ The Weibull distribution is identical to the exponential distribution.
- $B = 2$ The Weibull distribution is identical to the Rayleigh distribution.
- $B = 2.5$ The Weibull distribution approximates the lognormal distribution.
- $B = 3.6$ The Weibull distribution approximates the normal distribution.

Scale Parameter - $C$

The scale parameter only changes the scale of the density function along the $x$ axis. Some authors use $1/C$ instead of $C$ as the scale parameter. Although this is arbitrary, we prefer dividing by the scale parameter since that is how one usually scales a set of numbers.

The Weibull is specified in the program as $W(M, B)$, where $M$ is the mean which is given by

$$M = C \Gamma\left(1 + \frac{1}{B}\right).$$
Combining Distributions

This section discusses how distributions may be combined to form new distributions. Combining may be done in the form of algebraic manipulation, mixtures, or both.

Creating New Distributions using Expressions

The set of probability distributions discussed above provides a basic set of useful distributions. However, you may want to mimic reality more closely by combining these basic distributions. For example, paired data is often analyzed by forming the differences of the two original variables. If the original data are normally distributed, then the differences are also normally distributed. Suppose, however, that the original data are exponential. The difference of two exponentials is not a common distribution.

Expression Syntax

The basic syntax is

\[ C_1 \ D_1 \ \text{operator}_1 \ C_2 \ D_2 \ \text{operator}_2 \ C_3 \ D_3 \ \text{operator}_3 \ldots \]

where \( C_1, C_2, C_3, \) etc. are coefficients (numbers), \( D_1, D_2, D_3, \) etc. are probability distributions, and \( \text{operator} \) is one of the four symbols: +, -, *, /. Parentheses are only permitted in the specification of distributions.

Examples of valid expressions include

- \( N(4, 5) - N(4, 5) \)
- \( 2E(3) - 4E(4) + 2E(5) \)
- \( N(4, 2)/E(4)-K(5) \)

Notes about the coefficients: \( C_1, C_2, C_3 \)

The coefficients may be positive or negative decimal numbers such as 2.3, 5, or -3.2. If no coefficient is specified, the coefficient is assumed to be one.

Notes about the Distributions: \( D_1, D_2, D_3 \)

The distributions may be any of the distributions listed above such as normal, exponential, or beta. The expressions are evaluated by generating random values from each of the distributions specified and then combining them according to the operators.

Notes about the operators: +, -, *, /

All multiplications and divisions are performed first, followed by any additions and subtractions. Note that if only addition and subtraction are used in the expression, the mean of the resulting distribution is found by applying the same operations to the individual distribution means. If the expression involves multiplication or division, the mean of the resulting distribution is usually difficult to calculate directly.
Creating New Distributions using Mixtures

Mixture distributions are formed by sampling a fixed percentage of the data from each of several distributions. For example, you may model outliers by obtaining 95% of your data from a normal distribution with a standard deviation of 5 and 5% of your data from a distribution with a standard deviation of 50.

Mixture Syntax

The basic syntax of a mixture is

\[ D_1[W_1] ; D_2[W_2] ; \ldots ; D_k[W_k] \]

where the D’s represent distributions and the W’s represent weights. Note that the weights must be positive numbers. Also note that semi-colons are used to separate the components of the mixture.

Examples of valid mixture distributions include

- \( N(4, 5)[19] ; N(4, 50)[1] \) 95% of the distribution is \( N(4, 5) \), and the other 5% is \( N(4, 50) \).
- \( W(4, 3)[7] ; K(0)[3] \) 70% of the distribution is \( W(4, 3) \), and the other 30% is made up of zeros.
- \( N(4, 2)-N(4, 3)[2] ; E(4)*E(2)[8] \) 20% of the distribution is \( N(4, 2)-N(4, 3) \), and the other 80% is \( E(4)*E(2) \).

Notes about the distributions

The distributions D1, D2, D3, etc. may be any valid distributional expression.

Notes about the weights

The weights w1, w2, w3, etc. need not sum to one (or to one hundred). The program uses these weights to calculate new, internal weights that do sum to one. For example, if you enter weights of 1, 2, and 1, the internal weights will be 0.25, 0.50, and 0.25.

When a weight is not specified, it is assumed to have the value of ‘1.’ Thus

\( N(4, 5)[19] ; N(4,50)[1] \)

is equivalent to

\( N(4, 5)[19] ; N(4,50) \)
Procedure Options

This section describes the options that are specific to this procedure. These are located on the Data tab. To find out more about using the other tabs such as Labels or Plot Setup, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains the parameters used to specify a probability distribution.

Probability Distribution to be Simulated

Enter the components of the probability distribution to be simulated. One or more components may be entered from among the continuous and discrete distributions listed below the data-entry boxes. The model is specified in the first two boxes. The model is formed by joining the contents of these two boxes.

The $W$ parameter gives the relative weight of that component. For example, if you entered $P(5)[1];K(0)[2]$, about 33% of the random numbers would follow the $P(5)$ distribution, and 67% would be 0. When only one component is used, the value of $W$ may be omitted. For example, to generate data from the normal distribution with mean of five and standard deviation of one, you would enter $N(5, 1)$, not $N(5, 1)[1]$.

Each of the possible components were discussed earlier in the chapter.

Numbers in Histogram

This is the number of values generated from the probability distribution for display in the histogram. We recommend a value of about 5000.

Note that the histogram, box plot, and dot plot row limits must be set higher than this amount or the corresponding plot will not be displayed. These limits are modified by selecting Edit, Options, and Limits from the spreadsheet menu.

Numbers Stored

This is the number of values that are stored in the current database for use by NCSS in the column designated under the Storage tab. If this value is larger than the Numbers in Histogram value, it will be reset to that value.

If no column is specified in the Simulated Values box of the Storage tab, or if this value is zero, nothing will be stored on the database.

Usually, you will not need to store values on a database.

Force Positive

Checking this box will force all generated values to be positive. This is accomplished by taking the absolute value of each generated value.

Round to Integer

When checked, each value will be rounded off to an integer.
Example1 – Generating Normal Data

In this example, 5000 values will be generated from the standard normal (mean zero, variance one) distribution. These values will be displayed in a histogram and summarized numerically.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

Option | Value
--- | ---
Data Tab |  |
Probability Distribution | $N(0, 1)$
Numbers in Histogram | 5000
Numbers Stored | 0
Force Positive | not checked
Round to Integer | not checked

Annotated Output

Click the Run button to perform the calculations and generate the following output.

This report shows the histogram and a numerical summary of the 5000 simulate normal values. It is interesting to check how well the simulation did. Theoretically, the mean should be zero, the standard deviation one, the skewness zero, and the kurtosis three. Of course, your results will vary from these because these are based on generated random numbers.
Example2 – Generating Data from a Contaminated Normal

In this example, we will generate data from a contaminated normal. This will be accomplished by generating 95% of the data from a $N(100,3)$ distribution and 5% from a $N(110,15)$ distribution.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

This report shows the data from the contaminated normal. The mean is close to 100, but the standard deviation, skewness, and kurtosis have non-normal values. Note that there are now some very large outliers.
Example3 – Likert-Scale Data

In this example, we will generate data following a discrete distribution on a Likert scale. The distribution of the Likert scale will be 30% 1’s, 10% 2’s, 20% 3’s, 10% 4’s, and 30% 5’s.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example3 by clicking the Template tab and loading this template.

Example4 – Bimodal Data

In this example, we will generate data that have a bimodal distribution. We will accomplish this by combining data from two normal distributions, one with a mean of 10 and the other with a mean of 30. The standard deviation will be set at 4.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example4 by clicking the Template tab and loading this template.

Example5 – Gamma Data with Extra Zeros

In this example, we will generate data that have a gamma distribution, except that we will force there to be about 30% zeros. The gamma distribution will have a shape parameter of 5 and a mean of 10.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example5 by clicking the Template tab and loading this template.

Example7 – Difference of Two Identically Distributed Exponentials

In this example, we will demonstrate that the difference of two identically distributed exponential random variables follows a symmetric distribution. This is particularly interesting because the exponential distribution is skewed. In fact, the difference between any two identically distributed random variables follows a symmetric distribution.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example7 by clicking the Template tab and loading this template.

This report shows demonstrates that the distribution of the difference is symmetric.
Chapter 650

One Variance

Introduction

Occasionally, researchers are interested in the estimation of the variance (or standard deviation) rather than the mean. This module calculates the sample size and performs power analysis for hypothesis tests concerning a single variance.

Technical Details

Assuming that a variable $X$ is normally distributed with mean $\mu$ and variance $\sigma^2$, the sample variance is distributed as a Chi-square random variable with $N - 1$ degrees of freedom, where $N$ is the sample size. That is,

$$X^2 = \frac{(N-1)s^2}{\sigma^2}$$

is distributed as a Chi-square random variable. The sample statistic, $s^2$, is calculated as follows

$$s^2 = \frac{\sum_{i=1}^{N}(X_i - \bar{X})^2}{N - 1}.$$

The power or sample size of a hypothesis test about the variance can be calculated using the appropriate one of the following three formulas from Ostle (1988) page 130.

Case 1: $H_0: \sigma_1^2 = \sigma_0^2$ versus $H_a: \sigma_1^2 \neq \sigma_0^2$

$$\beta = P\left(\frac{\sigma_0^2}{\sigma_1^2} \chi^2_{\alpha/2,N-1} < \chi^2 < \frac{\sigma_0^2}{\sigma_1^2} \chi^2_{1-\alpha/2,N-1}\right)$$

Case 2: $H_0: \sigma_1^2 = \sigma_0^2$ versus $H_a: \sigma_1^2 > \sigma_0^2$

$$\beta = P\left(\chi^2 < \frac{\sigma_0^2}{\sigma_1^2} \chi^2_{1-\alpha,N-1}\right)$$

Case 3: $H_0: \sigma_1^2 = \sigma_0^2$ versus $H_a: \sigma_1^2 < \sigma_0^2$

$$\beta = P\left(\chi^2 > \frac{\sigma_0^2}{\sigma_1^2} \chi^2_{\alpha,N-1}\right)$$
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters.

V0 (Baseline Variance)

Enter one or more value(s) of the baseline variance. This variance will be compared to the alternative variance. It must be greater than zero.

Actually, only the ratio of the two variances (or standard deviations) is used, so you can enter a one here and enter the ratio value in the \( V1 \) box.

If Scale is \textit{Standard Deviation} this value is treated as a standard deviation rather than a variance.

V1 (Alternative Variance)

Enter one or more value(s) of the alternative variance. This variance will be compared to the baseline variance. It must be greater than zero.

Actually, only the ratio of the two variances (or standard deviations) is used, so you can enter a one for \( V0 \) and enter a ratio value here.

If Scale is \textit{Standard Deviation} this value is treated as a standard deviation rather than a variance.

N (Sample Size)

This is the number of observations in the study.

Known Mean

The degrees of freedom of the Chi-square test is \( N - 1 \) if the mean is calculated from the data (this is usually the case) or it is \( N \) if the mean is known. Check this box if the mean is known. This will cause an increase of the sample size by one.

Scale

Specify whether \( V0 \) and \( V1 \) are variances or standard deviations.
### Alternative Hypothesis

This option specifies the alternative hypothesis. This implicitly specifies the direction of the hypothesis test. The null hypothesis is always $H_0: \sigma_0^2 = \sigma_1^2$.

Note that the alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- **Ha: $V_0 \neq V_1$**. This selection yields a *two-tailed* test. Use this option when you are testing whether the variances are different but you do not want to specify beforehand which variance is larger.

- **Ha: $V_0 > V_1$**. The options yield a *one-tailed* test. Use it when you are only interested in the case in which $V_1$ is less than $V_0$.

- **Ha: $V_0 < V_1$**. This option yields a *one-tailed* test. Use it when you are only interested in the case in which $V_1$ is greater than $V_0$.

### Alpha

This option specifies one or more values for the significance level—probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

Values between 0.001 and 0.100 are common. The value of 0.05 has become the standard. This means that about one test in twenty will falsely reject the null hypothesis when it is actually true. Although 0.05 is the standard value, you should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Note that you can enter a range of values such as 0.01, 0.05 or 0.01 to 0.05 by 0.01.

### Beta (1-Power)

This option specifies one or more values for beta (the probability of accepting a false null hypothesis). Since statistical power is equal to one minus beta, specifying beta implicitly specifies the power. For example, setting beta at 0.20 also sets the power to 0.80.

Values must be between zero and one. The value of 0.20 has often used for beta. However, you should pick a value for beta that represents the risk of this type of error you are willing to take.

Note that you can enter a range of values such as 0.10, 0.20 or 0.05 to 0.20 by 0.05.

If your only interest is in determining the appropriate sample size for a confidence interval, set beta to 0.5.

### Options Tab

This tab sets a couple of options used in the iterative procedures.

### Maximum Iterations

Specify the maximum number of iterations allowed before the search for the criterion of interest is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank. A value of 500 is recommended.
Example1 - Calculating the Power

A machine used to perform a particular analysis is to be replaced with a new type of machine if the new machine reduces the variation in the output. The current machine has been tested repeatedly and found to have an output variance of 42.5. The new machine will be cost effective if it can reduce the variance by 30% to 29.75. If the significance level is set to 0.05, calculate the power for sample sizes of 10, 50, 90, 130, 170, 210, and 250.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions

Power is the probability of rejecting a false null hypothesis. It should be close to one. N is the size of the sample drawn from the population. V0 is the value of the population variance under the null hypothesis. V1 is the value of the population variance under the alternative hypothesis. Alpha is the probability of rejecting a true null hypothesis. It should be small. Beta is the probability of accepting a false null hypothesis. It should be small.

Summary Statements

A sample size of 10 achieves 14% power to detect a difference of 12.7500 between the null hypothesis variance of 42.5000 and the alternative hypothesis variance of 29.7500 using a one-sided, Chi-square hypothesis test with a significance level (alpha) of 0.050000.

This report shows the calculated power for each scenario.

Plot Section

This plot shows the power versus the sample size. We see that a sample size of about 150 is necessary to achieve a power of 0.90.
Example2 - Calculating Sample Size

Continuing with the previous example, the analyst wants to find the necessary sample sizes to achieve a power of 0.9, for two significance levels, 0.01 and 0.05, and for several variance values. To make interpreting the output easier, the analyst decides to switch from the absolute scale to a ratio scale. To accomplish this, the baseline variance is set at 1.0 and the alternative variances of 0.2, 0.3, 0.4, 0.5, 0.6, and 0.7 are tried.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

</tr>
</tbody>
</table>

$PASS$ calculated an $N$ of 13 which matches Davies’ result.
Chapter 655

Two Variances

Introduction
Occasionally, researchers are interested in comparing the variances (or standard deviations) of two groups rather than their means. This module calculates the sample sizes and performs power analyses for hypothesis tests concerning two variances.

Technical Details
Assuming that variables $X_1$ and $X_2$ are normally distributed variances $\sigma_1^2$ and $\sigma_2^2$ (the means are ignored), the distribution of the ratio of the sample variances follows the $F$ distribution. That is,

$$F = \frac{s_1^2}{s_2^2}$$

is distributed as an $F$ random variable with $N_1 - 1$ and $N_2 - 1$ degrees of freedom. The sample statistic, $s_j^2$, is calculated as follows

$$s_j^2 = \frac{\sum_{i=1}^{N_j} (X_{ji} - \bar{X}_j)^2}{N_j - 1}.$$

The power or sample size of a hypothesis test about the variance can be calculated using the appropriate one of the following three formulas:

Case 1: $H_0: \sigma_1^2 = \sigma_2^2$ versus $H_a: \sigma_1^2 \neq \sigma_2^2$

$$\beta = P\left(\frac{\sigma_1^2}{\sigma_2^2} F_{\frac{1}{2},N_1-1,N_2-1} < F < \frac{\sigma_1^2}{\sigma_2^2} F_{1-\alpha/2,N_1-1,N_2-1}\right)$$

Case 2: $H_0: \sigma_1^2 = \sigma_2^2$ versus $H_a: \sigma_1^2 > \sigma_2^2$

$$\beta = P\left(F > \frac{\sigma_1^2}{\sigma_2^2} F_{\alpha,N_1-1,N_2-1}\right)$$

Case 3: $H_0: \sigma_1^2 = \sigma_2^2$ versus $H_a: \sigma_1^2 < \sigma_2^2$

$$\beta = P\left(F < \frac{\sigma_1^2}{\sigma_2^2} F_{1-\alpha,N_1-1,N_2-1}\right)$$
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters.

V1 and V2

Enter one or more value(s) for the variances of the groups, $\sigma_1^2$ and $\sigma_2^2$. All entries must be greater than zero.

Note that since the ratio of these variances is all that is used in the power equations, you can specify the problem in terms of the variance ratio instead of the two variances. To do this, enter 1.0 for $V2$ and enter the desired variance ratio in $V1$.

If Scale is Standard Deviation this value is the standard deviation rather than the variance.

Alpha

This option specifies one or more values for the significance level--probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

Values between 0.001 and 0.100 are acceptable. The value of 0.05 has become the standard. This means that about one test in twenty will falsely reject the null hypothesis when it is actually true.

Although 0.05 is the standard value, you should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Note that you can enter a range of values such as $0.01,0.05$ or $0.01$ to $0.05$ by $0.01$.

Beta (1-Power)

This option specifies one or more values for beta (the probability of accepting a false null hypothesis). Since statistical power is equal to one minus beta, specifying beta implicitly specifies the power. For example, setting beta at 0.20 also sets the power to 0.80.

Values must be between zero and one. The value of 0.20 has often used for beta. However, you should pick a value for beta that represents the risk of this type of error you are willing to take.

Note that you can enter a range of values such as $0.10,0.20$ or $0.05$ to $0.20$ by $0.05$.

If your only interest is in determining the appropriate sample size for a confidence interval, set beta to 0.5.

Scale

Specify whether $V1$ and $V2$ are variances or standard deviations.
Alternative Hypothesis

This option specifies the alternative hypothesis. This implicitly specifies the direction of the hypothesis test. The null hypothesis is always $H_0: \sigma_1^2 = \sigma_2^2$.

Note that the alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- **$H_a: \sigma_1 \neq \sigma_2$**. This selection yields a *two-tailed* test. Use this option when you are testing whether the variances are different but you do not want to specify beforehand which variance is larger.

- **$H_a: \sigma_1 > \sigma_2$**. The options yields a *one-tailed* test. Use it when you are only interested in the case in which $\sigma_2$ is less than $\sigma_1$.

- **$H_a: \sigma_1 < \sigma_2$**. This option yields a *one-tailed* test. Use it when you are only interested in the case in which $\sigma_2$ is greater than $\sigma_1$.

**N1 (Sample Size Group 1)**

Enter a value (or range of values) for the sample size of this group. Note that these values are ignored when you are solving for $N_1$. You may enter a range of values such as 10 to 100 by 10.

**N2 (Sample Size Group 2)**

Enter a value (or range of values) for the sample size of group 2 or enter *Use R* to base $N_2$ on the value of $N_1$. You may enter a range of values such as 10 to 100 by 10.

*Use R*

When *Use R* is entered, $N_2$ is calculated using the formula

$$N_2 = \lceil R \times N_1 \rceil$$

where $R$ is the Sample Allocation Ratio and $\lceil Y \rceil$ is the first integer greater than or equal to $Y$. For example, if you want $N_1 = N_2$, select *Use R* here and set $R = 1$.

**R (Sample Allocation Ratio)**

Enter a value (or range of values) for $R$, the allocation ratio between samples. This value is only used when $N_2$ is set to *Use R*.

When used, $N_2$ is calculated from $N_1$ using the formula: $N_2 = \lceil R \times N_1 \rceil$ where $\lceil Y \rceil$ is the next integer greater than or equal to $Y$. Note that setting $R = 1.0$ forces $N_2 = N_1$.

**Options Tab**

This tab sets a couple of options used in the iterative procedures.

**Maximum Iterations**

Specify the maximum number of iterations allowed before the search for the criterion of interest is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank. A value of 500 is recommended.
Example 1 - Calculating the Power

A machine used to perform a particular analysis is to be replaced with a new type of machine if the new machine reduces the variance in the output by 50%. If the significance level is set to 0.05, calculate the power for sample sizes of 5, 10, 20, 35, 50, 90, 130, and 200.

Setup

You can enter these values yourself or load the Example 1 template from the Template tab.

Report Definitions
- Power is the probability of rejecting a false null hypothesis. It should be close to one.
- N1 is the size of the sample drawn from the population 1.
- N2 is the size of the sample drawn from the population 2.
- V1 is the value of the population variance of group 1.
- V2 is the value of the population variance of group 2.
- Alpha is the probability of rejecting a true null hypothesis. It should be small.
- Beta is the probability of accepting a false null hypothesis. It should be small.

Summary Statements
Group sample sizes of 5 and 5 achieve 3% power to detect a ratio of 2.0000 between the group one variance of 1.0000 and the group two variance of 0.5000 using a one-sided F test with a significance level (alpha) of 0.010000.

This report shows the calculated power for each scenario.

Plot Section

This plot shows the power versus the sample size for the two significance levels. It is now easy to determine an appropriate sample size to meet both the alpha and beta objectives of the study.
Example2 - Calculating Sample Size

Continuing with the previous example, the analyst wants to find the necessary sample sizes to achieve a power of 0.9 for two significance levels, 0.01 and 0.05, and for several variance ratio values of 0.2, 0.3, 0.4, 0.5, 0.6, and 0.7.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

This report shows the necessary sample size for each scenario.
This plot shows the necessary sample size for various values of $V2$. Note that as $V2$ nears $V1$, the sample size is increased.
Example3 - Validation Using Davies

Problem Statement
Davies (1971) page 41 presents an example with $V_1 = 4$, $V_1 = 1$, $\alpha = 0.05$, and $\text{Power} = 0.99$ in which the sample sizes, $N_1$ and $N_2$, are calculated to be 36. We will run this example through PASS.

Setup
You can enter these values yourself or load the Example3 template from the Template tab.

PASS calculated the $N_1$ and $N_2$ to be 36 which matches Davies’ result.
Chapter 700

Log-Rank Test (Simple)

Introduction

This module allows the sample size and power of the log-rank test to be analyzed under the assumption of proportional hazards. Time periods are not stated. Rather, it is assumed that enough time elapses to allow for a reasonable proportion of responses to occur. If you want to study the impact of accrual and follow-up time, you should use the advanced log-rank module also contained in PASS. The formulas used in this module come from Machin et al. (1997).

A clinical trial is often employed to test the equality of survival distributions for two treatment groups. For example, a researcher might wish to determine if Beta-Blocker A enhances the survival of newly diagnosed myocardial infarction patients over that of the standard Beta-Blocker B. The question being considered is whether the pattern of survival is different.

The two-sample t-test is not appropriate for two reasons. First, the data consist of the length of survival (time to failure), which is often highly skewed, so the usual normality assumption cannot be validated. Second, since the purpose of the treatment is to increase survival time, it is likely (and desirable) that some of the individuals in the study will survive longer than the planned duration of the study. The survival times of these individuals are then said to be censored. These times provide valuable information, but they are not the actual survival times. Hence, special methods have to be employed which use both regular and censored survival times.

The log-rank test is one of the most popular tests for comparing two survival distributions. It is easy to apply and is usually more powerful than an analysis based simply on proportions. It compares survival across the whole spectrum of time, not at just one or two points.

The power calculations used here assume an underlying exponential distribution. However, we are rarely in a position to assume exponential survival times in an actual clinical trial. How do we justify the exponential survival time assumption? First, the log-rank test and the test derived using the exponential distribution have nearly the same power when the data are in fact exponentially distributed. Second, under the proportional hazards model (which is assumed by the log-rank test), the survival distribution can be transformed to be exponential and the log-rank test remains the same under monotonic transformations.

Technical Details

In order to define the input parameters, we will present below some rather complicated looking formulas. You need not understand the formulas. However, you should understand the individual parameters used in these formulas.
We assume that a study is to be made comparing the survival of an existing (control) group with an experimental group. The control group consists of patients that will receive the existing treatment. In cases where no existing treatment exists, the control group consists of patients that will receive a placebo. This group is arbitrarily called group one. The experimental group will receive the new treatment. It is called group two.

We assume that the critical event of interest is death and that two treatments have survival distributions with instantaneous death (hazard) rates, \( \lambda_1 \) and \( \lambda_2 \). These hazard rates are an subject’s probability of death in a short period of time. We want to test hypotheses about these hazard rates.

**Hazard Ratio**

There are several ways to express the difference between two hazard rates. One way is to calculate the difference, \( \lambda_1 - \lambda_2 \). Another way is to form the hazard ratio (HR):

\[
HR = \frac{\lambda_2}{\lambda_1}.
\]

Note that since HR is formed by dividing the hazard rate of the experimental group by that of the control group, a treatment that does better than the control will have a hazard ratio that is less than one.

The hazard ratio may be formulated in other ways. If the proportions surviving during the study are called \( S1 \) and \( S2 \) for the control and experimental groups, the hazard ratio is given by

\[
HR = \frac{\log(S2)}{\log(S1)}.
\]

Furthermore, if the median survival times of the two groups are \( M1 \) and \( M2 \), the hazard ratio is given by

\[
HR = \frac{M1}{M2}.
\]

Each of these expressions for the difference between hazards rates is useful in some situations. There is no one best way, so you will have to be a little flexible.
Log-Rank Test

We assume that the log-rank test will be used to analyze the data once they are collected. Basing the power calculations on the log-rank test, we arrive at the following formula that gives the power based on several other parameters:

\[ z_{1-\beta} = \frac{HR - 1}{\sqrt{N(1-w)\phi\left[1-S1\right] + \phi\left[1-S2\right]}} / (1 + \phi) \]

where \( k \) is 1 for a one-sided hypothesis test or 2 for a two-sided test, \( \alpha \) and \( \beta \) are the error rates defined as usual, the \( z \)'s are the usual points from the standard normal distribution, \( w \) is the proportion that are lost to follow up, and \( \phi \) represents the sample size ratio between the two groups. That is, \( p_1 \) is the proportion of the total sample size that is in the control group, \( \phi \) is given by

\[ \phi = \frac{1 - p_1}{p_1} \]

Note that the hypothesis being tested is that the hazard rates are equal:

\[ H_0: \lambda_1 = \lambda_2 \]

This formulation assumes that the hazard rates are proportional. It does not assume that the failure times are exponentially distributed.

Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are Proportion Surviving 1, Proportion Surviving 2, \( N \), Alpha, or Beta. Under most situations, you will select either Beta or \( N \).

Select \( N \) when you want to calculate the sample size needed to achieve a given power and alpha level.

Select \( Beta \) when you want to calculate the power of an experiment that has already been run.

If you select Survive 1, the search is made for values that are less than \( S2 \). Likewise, if you select Survive 2, the search is made for values that are greater than \( S1 \).
S1, Proportion Surviving 1

$S_1$ is the proportion of patients belonging to group 1 (controls) that are expected to survive during the study. Since $S_1$ is a proportion, it must be between zero and one. A value for $S_1$ must be determined either from a pilot study or from previous studies.

S2, Proportion Surviving 2

$S_2$ is the proportion of patients belonging to group 2 (experimental) that are expected to survive during the study. Since $S_2$ is a proportion, it must be between zero and one. This value is not necessarily the expected survival proportion under the treatment. Rather, you may set it to that value that, if achieved, would be of special interest. Values below this amount would not be of interest.

For example, if the standard 1-year survival proportion is 0.2 and the new treatment raises this proportion to 0.3 (a 50% increase in the proportion surviving), others may be interested in using it.

Sometimes, researchers wish to state the alternative hypothesis in terms of the hazard ratio, $HR$, rather than the value of $S_2$. Using the fact that

$$HR = \frac{\text{Log}(S_2)}{\text{Log}(S_1)}$$

we can solve for $S_2$ to obtain

$$S_2 = \exp(\text{Log}(S_1)HR).$$

Using this equation, you can determine an appropriate value for $S_2$ from a value for $HR$.

For example, suppose $S_1$ is 0.4 and you have determined that if the hazard rate is reduced by half, the improvement is sufficient to justify a change in treatment. The appropriate value for $S_2$ is $\exp(\text{Log}(0.4)(0.5)) = 0.632$.

When you do not have an anticipated value for $HR$, you can find an estimate base on the Median Survival Times ($M_1$ and $M_2$) since $HR = M_1/M_2$.

Total Sample Size (N)
The combined sample size of both groups.

Proportion in Group 1

The proportion of the sample size ($N$) that is assigned to the first group. The rest of the patients are assigned to the second group. When exact values are not available, the number in group one is found by rounding up to the next integer. The number in group two is found by subtraction.

Alpha

This option specifies one or more values for the probability of a type-I error, alpha. This is also called the significance level or test size. A type-I error occurs when you reject the null hypothesis of equal survival curves when in fact the curves are equal.

Values of alpha must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.
The check box lets you indicate whether you want to run a one-sided or two-sided test. In most cases, you should run a two-sided test unless you have a legitimate reason to run the one-sided test.

**Beta (1-Power)**

This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of survival curves when in fact the curves are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is becoming common. You should pick a value that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.

**Example 1 - Finding the Power**

An experiment has been conducted to test the effectiveness of a new treatment on a total of 100 patients. The current treatment for this disease achieves 50% survival after two years. The proportion in the treatment group that survived two years was 0.70. Testing was done at the 0.05 significance level. Even though there was an increase of 0.20 for 0.50 to 0.70, the log-rank test did not reject the hypothesis of equal hazard rates for the two treatments. Study the power of this test.

**Setup**

You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

### Report Definitions

- **Power** is the probability of rejecting a false null hypothesis.
- **N** is the combined sample size.
- **N1** sample size in group 1.
- **N2** sample size in group 2.
- **S1** is the proportion surviving in group 1.
- **S2** is the proportion surviving in group 2.
- The **Hazard Ratio** is the ratio of hazard2 and hazard1. It is \( \frac{\log(S_2)}{\log(S_1)} \).
- **Alpha** is the probability of rejecting a true null hypothesis.
- **Beta** is the probability of accepting a false null hypothesis.

### Summary Statements

A two-sided log rank test with an overall sample size of 50 subjects (of which 25 are in group 1 and 25 are in group 2) achieves 30% power at a 0.0500 significance level to detect a difference of 0.2000 between 0.5000 and 0.7000—the proportions surviving in groups 1 and 2, respectively. This corresponds to a hazard ratio of 0.5000. The proportion of patients lost during follow up was 0.0000. These results are based on the assumption that the hazard rates are proportional.

This report shows the values of each of the parameters, one scenario per row. The values from this table are in the chart below.

### Plots Section

This plot shows the relationship between alpha and power in this example. We notice that for alpha = 0.05, a power of 0.80 is reached when the sample size is about 200. A power of 90% is reached when the sample size is 250. Hence, we realize that this study should have had at least twice the number of patients that it had.
Example 2 - Finding the Sample Size

Continuing with our example, the researcher decides that he wants to do it right this time. He believes that if the survival proportion of the treatment group is 0.6 or better, people will begin to use his treatment. He wants to know how many subjects he needs.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

Annotated Output

Click the Run button to perform the calculations and generate the following output.

Results

We will consider the chart since that allows us to understand the patterns more quickly. We note that changing $S_2$ from 0.60 (the top line) to 0.62 (the middle line) decreases the sample size requirements by almost half. Our researcher decides to take a sample of 500 patients. This will achieve almost 80% power in detecting a shift from 0.50 to 0.62 in survivability.
Example 3 - Validation using Machin

Machin et al. (1997) page 180 gives an example in which $S_1$ is 0.25, $S_2$ is 0.50, the one-sided significance level is 0.05, and the power is 90%. The total sample size is 124. We will now run this example through PASS.

Setup
You can enter these values yourself or load the Example3 template from the Template tab.

PASS also calculated the total sample size to be 124.
Chapter 705

Log-Rank Survival Test (Advanced)

Introduction

This module computes the sample size and power of the log-rank test for equality (or non-inferiority) of survival distributions under the assumption of proportional hazards. Accrual time and follow-up time are included among the parameters to be set.

A clinical trial is often employed to test the equality of survival distributions for two treatment groups. For example, a researcher might wish to determine if Beta-Blocker A enhances the survival of newly diagnosed myocardial infarction patients over that of the standard Beta-Blocker B. The question being considered is whether the pattern of survival is different.

The two-sample t-test is not appropriate for two reasons. First, the data consist of the length of survival (time to failure), which is often highly skewed, so the usual normality assumption cannot be validated. Second, since the purpose of the treatment is to increase survival time, it is likely (and desirable) that some of the individuals in the study will survive longer than the planned duration of the study. The survival times of these individuals are then said to be censored. These times provide valuable information, but they are not the actual survival times. Hence, special methods have to be employed which use both regular and censored survival times.

The log-rank test is one of the most popular tests for comparing two survival distributions. It is easy to apply and is usually more powerful than an analysis based simply on proportions. It compares survival across the whole spectrum of time, not just at one or two points. This module allows the sample size and power of the log-rank test to be analyzed under very general conditions.

Power and sample size calculations for the log-rank test have been studied by several authors. PASS uses the methods of Lachin and Foulkes (1986) because of their generality. Although small differences among methods can be found depending upon which assumptions are adopted, there is little practical difference between the techniques.

The power calculations used here assume an underlying exponential distribution. However, this assumption is rarely accurate in an actual clinical trial. How is this assumption justified? First, the log-rank test and the test derived using the exponential distribution have nearly the same power when the data are in fact exponentially distributed. Second, under the proportional hazards model (which is assumed by the log-rank test), the survival distribution can be transformed to exponential and the log-rank test remains the same under monotonic transformations.
Technical Details

Some rather complicated formulas are used to define the input parameters. You need not understand the formulas. However, you should understand the individual parameters used in these formulas.

Basic Model

Suppose a clinical trial consists of two independent treatment groups labeled ‘1’ and ‘2’ (you could designate group one as the control group and group two as the treatment group). If the total sample size is \( N \), the sizes of the two groups are \( n_1 \) and \( n_2 \). Usually, you would plan to have \( n_1 = n_2 \). Define the proportion of the total sample in each group as

\[
Q_i = \frac{n_i}{N}, \quad i = 1, 2
\]

Individuals are recruited during an accrual period of \( R \) years (or months or days). They are followed for an additional period of time until a total of \( T \) years is reached. Hence, the follow-up period is \( T - R \) years. At the end of the study, the log-rank test is conducted at significance level \( \alpha \) with power \( 1 - \beta \).

If we assume an exponential model with hazard rates \( \lambda_1 \) and \( \lambda_2 \) for the two groups, Lachin and Foulkes (1986, Eq. 2.1) establish the following equation relating \( N \) and power:

\[
\sqrt{N} |\lambda_1 - \lambda_2| = Z_\alpha \sqrt{\phi(\lambda) \left( \frac{1}{Q_1} + \frac{1}{Q_2} \right)} + Z_\beta \sqrt{\frac{\phi(\lambda_1) + \phi(\lambda_2)}{Q_1} + \frac{\phi(\lambda_1) + \phi(\lambda_2)}{Q_2}}
\]

where

\[
\lambda = Q_1 \lambda_1 + Q_2 \lambda_2
\]

\[
\phi(\lambda) = N \sigma^2(\hat{\lambda})
\]

\[
Z_\alpha = \Phi(1 - \theta)
\]

\( \Phi(z) \) is the area to the left of \( z \) under the standard normal density, \( \hat{\lambda} \) is the maximum likelihood estimate of \( \lambda \), and that \( \sigma^2(\hat{\lambda}) \) represents the variance of \( \hat{\lambda} \).
Exponential Distribution

The hazard rate from the exponential distribution, $\lambda$, is usually estimated using maximum likelihood techniques. In the planning stages, you have to obtain an estimate of this parameter. To see how to accomplish this, let’s briefly review the exponential distribution. The density function of the exponential is defined as

$$f(t) = \lambda e^{-\lambda t}, \quad t \geq 0, \lambda > 0.$$  

The cumulative survival distribution function is

$$S(t) = e^{-\lambda t}, \quad t \geq 0.$$  

Solving this for $\lambda$ yields

$$\lambda = -\frac{\log(S(t))}{t}.$$  

Note that $S(t)$ gives the probability of surviving $t$ years. To obtain a planning estimate of $\lambda$, you need only know the proportion surviving during a particular time period. You can then use the above equation to calculate $\lambda$.

**Patient Entry**

Patients are enrolled during the accrual period. **PASS** lets you specify the pattern in which subjects are enrolled. Suppose patient entry times are distributed as $g(t)$ where $t_i$ is the entry time of the $i^{th}$ individual and $0 \leq t_i \leq R$. Let $g(t)1$ follow the truncated exponential distribution with parameter $A$, which has the density

$$g(t) = \begin{cases} 
A e^{-At}, & 0 \leq t \leq R, \quad A \neq 0 \\
1/R, & 0 \leq t \leq R, \quad A = 0
\end{cases}$$

Note that $R$ is accrual time. The corresponding cumulative distribution function is

$$G(t) = \begin{cases} 
1 - e^{-At}, & 0 \leq t \leq R, \quad A \neq 0 \\
1/e^{-AR}, & 0 \leq t \leq R, \quad A = 0
\end{cases}$$

$A$ is interpreted as follows.

$A > 0$ results in a convex (faster than expected) entry distribution.

$A < 0$ results in a concave (slower than expected) entry distribution.

$A = 0$ results in the uniform entry distribution in which $g(t) = 1/R$.

Rather than specify $A$ directly, **PASS** has you enter the percentage of the accrual time that will be needed to enroll 50% of the subjects. Using an iterative search, the value of $A$ corresponding to this percentage is calculated and used in the calculations.
Losses to Follow-Up

The staggered patient entry over the accrual period results in censoring times ranging from $T - R$ to $T$ years during the follow-up period. This is often referred to as administrative censoring, since it is caused by the conclusion of the study rather than by some random factor working on an individual. To model the losses to follow-up which come from other causes, we use the exponential distribution with hazard rates $\eta_1$ and $\eta_2$. Since these rates are difficult and confusing to define directly, PASS lets you input the proportion lost due to other causes over a specified period of time and uses the following equation to determine the hazard rates:

$$\eta = \frac{\log(1 - P(i))}{t}$$

General Model

Combining all these parameters into the model results in

$$\phi(\lambda, \eta, \gamma) = \lambda^2 \left( \frac{\lambda}{\lambda + \eta} + \frac{\lambda \gamma e^{(\lambda + \eta)T}}{1 - e^{\lambda + \eta - T}} \right)^{-1}.$$ 

This expression may then be used in an equation that relates these parameters to sample size and power

$$\sqrt{N|\lambda_1 - \lambda_2|} = Z_{0.025} \sqrt{\phi(\lambda) \left( \frac{1}{Q_1} + \frac{1}{Q_2} \right)} + Z_{1-\beta} \sqrt{\phi(\lambda_1) \phi(\lambda_2) \frac{Q_1}{Q_2}}.$$
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are Proportion Surviving 1, Proportion Surviving 2, Accrual, Follow-Up, Alpha, Beta, and N. Under most situations, you will select either Beta or N.

Select N when you want to calculate the sample size needed to achieve a given power and alpha level.

Select Beta when you want to calculate the power.

S1 and S2 (Proportion Surviving Past T0)

Specify the proportion of patients in each group that survive until after T0. These quantities are called S1 and S2. The value of T0 is given in the Fixed Time Point box. For example, if the Fixed Time parameter is 3 and this value is set to 0.7, then 70% of the patients survive at least 3 years. Note that since this is a proportion, values must be between zero and one.

These quantities are used as a convenient method of entering the hazard rates $\lambda_1$ and $\lambda_2$. The first group is arbitrarily designated as the control group and the second group is arbitrarily designated as the treatment group.

The hazard rates are calculated from the proportions surviving using the formulas

$$\lambda_1 = -\frac{\log(S1)}{T0} \text{ and } \lambda_2 = -\frac{\log(S2)}{T0}$$

If your sample size problem is cast in terms of hazard rates, the proportions surviving are calculated using the formula

$$S1 = \exp(-\lambda_1 t) \text{ and } S2 = \exp(-\lambda_2 t)$$

Accrual Time

The accrual time is the length of time during which patients enter the study. It is the value of $R$. 
% Time Until 50% Accrual

This specifies the percentage of the accrual time needed to enroll 50% of the patients. This value is converted into a value for $A$, the patient entry parameter. Use this option to indicate how subjects are enrolled during the accrual period. For example, in one study, it may be possible to enroll a number of patients early on, while in another study, most of the subjects will be enrolled near the end of the accrual period.

Values between 1 and 97 may be entered.

If you expect uniform patient entry, enter 50. Unless you know that patient enrollment will not be uniform during the accrual period, you should use this amount.

If you expect more patients to enter during the early part of the accrual period, enter an amount less than 50 such as 30. A 30 here means that 50% of the patients will have been enrolled when 30% of the accrual time has elapsed.

If you expect more patients to enter during the later part of the accrual period, enter an amount greater than 50 such as 70. A 70 here means that 50% of the patients will have been enrolled when 70% of the accrual time has elapsed.

PASS assumes that patient entry times follow the truncated exponential distribution. This parameter controls the shape and scale of that distribution.

Follow-Up Time

The follow-up time is the length of time between the entry of the last individual into the study and the end of the study. Since $T$ is the total length of the study and $R$ is the accrual time, the follow-up time is $T-R$.

Follow-Up Loss (1 and 2)

This is the proportion in this group that is lost to follow-up during the Fixed Time Period, $T0$. Using this value, the lost-to-follow-up hazard rate is calculated using the exponential distribution as it is with $S(t)$. The equation used to convert these proportions into $\eta_1$ and $\eta_2$ is:

$$\eta_i = -\log\left(1 - P_i(T0)\right) / T0$$

Here $P(T0)$ is the proportion lost to follow up from the beginning of the study until $T0$. So if $T0$ is 3 years and 10% of the patients in group one are lost to follow-up

$$\eta_1 = -\log(1 - 0.1) / 3$$

$$= 0.03512$$

Values between zero and one are valid. Zero is used to indicate no loss to follow-up.
**Alternative Hypothesis**
This option specifies the alternative hypothesis in terms of the proportion surviving in each group. This implicitly specifies the direction of the hypothesis test. The null hypothesis is always $H_0: S_1 = S_2$.

Note that the alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- **Ha: $S_1 \neq S_2$**. This is the usual selection. It yields the *two-tailed* t-test. Use this option when you are testing whether the survival curves are different, but you do not want to specify beforehand which curve is better.

- **Ha: $S_1 < S_2$**. This option yields a *one-tailed* test. Use it when you are only interested in the case in which the survival in group one is less than that for group two.

- **Ha: $S_1 > S_2$**. This option yields a *one-tailed* test. Use it when you are only interested in the case in which the survival in group one is greater than that for group two.

**T0 (Fixed Time Point)**
This is the time period used to convert the proportions given in Proportion Surviving 1, Proportion Surviving 2, Follow-Up Loss1, and Follow-Up Loss2 into hazard rates. If you enter 0.4 in Proportion Survive1 and a 3 here, you are indicating that 40% survive longer than 3 years.

**N (Total Sample Size)**
This is the combined sample size of both groups. This amount is divided between the two groups using the value of the Proportion in Group 1.

**Proportion in Group 1**
This is the proportion of $N$ in group one. If this value is labeled $p_1$, the sample size of group one is $Np_1$ and the sample size of group two is $N - Np_1$. Note that the value of $Np_1$ is rounded to the nearest integer.

**Alpha (Significance Level)**
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal survival curves when in fact the curves are equal.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.
Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal survival curves when in fact the curves are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is becoming more popular. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
Example 1 - Finding the Power

A researcher is planning a clinical trial using a parallel, two-group, equal sample allocation design to compare the survivability of a new treatment with that of the current treatment. The proportion surviving one-year after the current treatment is 0.50. The new treatment will be adopted if the proportion surviving after one year increases to 0.75.

The trial will include a recruitment period of one-year after which participants will be followed for an additional two-years. It is assumed that patients will enter the study uniformly over the accrual period. The researcher estimates a loss-to-follow rate of 15% during the first year in both the control and the experimental groups.

The researcher decides to investigate various sample sizes between 10 and 250 at both the 0.01 and 0.05 significance levels.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

**Percent of accrual time until 50% enrollment is reached:** 50.00%

---

**Report Definitions**

Power is the probability of rejecting a false null hypothesis. Power should be close to one.

Alpha is the probability of rejecting a true null hypothesis. It should be small.

Beta is the probability of accepting a false null hypothesis. It should be small.

---

**Summary Statements**

A two-sided log rank test with an overall sample size of 10 subjects (of which 5 are in group 1 and 5 are in group 2) achieves 7% power at a 0.01000 significance level to detect a difference of 0.25000 between 0.50000 and 0.75000—the proportions surviving in groups 1 and 2 after 1.00 time periods. Patients entered the study during an accrual period of 2.00 time periods. 50% of the enrollment was complete when 50.00% of the accrual time had past. A follow-up period of 1.00 time periods had a 15.0% loss from group 1 and a 15.0% loss from group 2.

---

This report shows the values of each of the parameters, one scenario per row. Note that approximately 100 patients, 50 per group, will be needed to achieve about 90% power at the 0.05 significance level.

---

**Plots Section**

This plot shows the relationship between sample size and power for the two significance levels.
Example 2 - Finding the Sample Size

Continuing with the previous example, the researcher wants to investigate the sample size necessary to achieve 80% or 90% power for various values of the proportion surviving in the treatment group from 0.55 to 0.80 at the 0.05 significance level. All other parameters will remain the same.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

</table>
This study shows the huge increase in sample size necessary to detect values of $S_2$ below 0.65. It also shows that roughly 35% more participants are required for 90% power than for 80% power in this situation.
Example 3 - Validation using Lachin and Foulkes

Lachin and Foulkes (1986), the developers of formulas used in this routine, give an example on page 509 in which $\lambda_1 = 0.30$, $\lambda_2 = 0.20$, $N = 378$, $\alpha = 0.05$ (one-sided), $R = 3$, $T = 3$, and $\beta = 0.10$. There is no loss to follow up and uniform patient entry is assumed.

The first step is to determine the proportion surviving at the end of one year for each group using the formula:

$$ S(t) = e^{-\lambda t} $$

For group 1 we have

$$ S_1(1) = e^{-0.3(1)} $$

$$ = 0.74081822 $$

For group 2 we have

$$ S_2(1) = e^{-0.2(1)} $$

$$ = 0.81873075 $$

Setup

Example 4 - Non-Inferiority Test

This example will show how to use this module to calculate power and sample size for non-inferiority trials. Remember that non-inferiority is established by showing that the new treatment is no worse than the standard treatment, except for a small amount called the margin of equivalence.

Consider the following example. Suppose the median survival time of the standard drug is 15 months. Unfortunately, this drug has serious side effects. A promising new drug has been developed that has much milder side effects. A non-inferiority trial is to be designed to show that the new drug is not inferior to the standard drug. The margin of equivalence is set at 3 months, so, to establish non-inferiority, the study has to conclude that the median survival time of the new drug is at least 12 months.

The trial will accept subjects for 18 months. It will continue for an additional 6 months after the accrual period. Although the study planners anticipate some dropout, they want to begin their analysis without considering dropout. They set the significance level at 0.05. They want to determine the necessary sample size to achieve 80% and 90% power. The calculations proceed as follows.

Use the Survival Parameter Conversion Window to convert the 'median survival rates' to 'proportions surviving' so that they can be entered into the panel. Press the Sv button that is above the S1 box to display this window. Enter 24 for T0, 12 for Median Survival Time 1, and 15 for Median Survival Time 2. The screen will appear as follows.

Thus, a sample size of about 663 per group would be needed for 80% power, and a sample of 479 per group would be needed for 90% power.
Chapter 710

Group Sequential Tests of Two Survival Curves

Introduction

Clinical trials are longitudinal. They accumulate data sequentially through time. The participants cannot be enrolled and randomized on the same day. Instead, they are enrolled as they enter the study. It may take several years to enroll enough patients to meet sample size requirements. Because clinical trials are long term studies, it is in the interest of both the participants and the researchers to monitor the accumulating information for early convincing evidence of either harm or benefit. This permits early termination of the trial.

Group sequential methods allow statistical tests to be performed on accumulating data while a phase III clinical trial is ongoing. Statistical theory and practical experience with these designs have shown that making four or five interim analyses is almost as effective in detecting large differences between treatment groups as performing a new analysis after each new data value. Besides saving time and resources, such a strategy can reduce the experimental subject’s exposure to an inferior treatment and make superior treatments available sooner.

When repeated significance testing occurs on the same data, adjustments have to be made to the hypothesis testing procedure to maintain overall significance and power levels. The landmark paper of Lan & DeMets (1983) provided the theory behind the alpha spending function approach to group sequential testing. This paper built upon the earlier work of Armitage, McPherson, & Rowe (1969), Pocock (1977), and O’Brien & Fleming (1979). PASS implements the methods given in Reboussin, DeMets, Kim, & Lan (1992) to calculate the power and sample sizes of various group sequential designs.

This module calculates sample size and power for group sequential designs used to compare two survival curves. Other modules perform similar analyses for the comparison of means and proportions. The program allows you to vary number and times of interim tests, type of alpha spending function, and test boundaries. It also gives you complete flexibility in solving for power, significance level, sample size, or effect size. The results are displayed in both numeric reports and informative graphics.
Technical Details

In many clinical trials, patients are recruited and randomized to receive a particular treatment, either experimental or control, and then monitored until either a critical event occurs or the study is ended. The length of time the patient is monitored until the critical event occurs is called the **follow-up time**. After the study is ended, the follow-up times of the patients in the two groups are compared using the **logrank test** in what is often called a **survival analysis**.

When the critical event does not occur for a patient by the time the study is ended, the follow-up time is said to have been **censored**. Although the actual event time is not known for this patient, it is known that the event time will be greater than the follow-up time. Hence, some information is gleaned from these participants. Because of this censoring, the usual tests of means or proportions cannot be used. The logrank test was developed to provide a statistical test comparing the efficacy of the two treatments.

**The Hazard Ratio (HR)**

Suppose the critical event is death. The survival distribution of each treatment can be characterized by the instantaneous death rates, \( \lambda_1 \) and \( \lambda_2 \). An instantaneous death rate, often called the **hazard**, is the probability of death in a short interval of time. The comparison of the efficacies of the two treatments is often formalized by considering the ratio of the hazard, or **hazard ratio** (HR).

\[
HR = \frac{\lambda_2}{\lambda_1}
\]

Although the logrank test concerns the ratio of the hazard rates of the two groups, when planning a study, it may be easier to obtain information about the expected proportion surviving during the trial. It turns out that the hazard ratio can be computed from the survival proportions, \( S_1 \) and \( S_2 \), using the equation

\[
HR = \frac{\log(S_2)}{\log(S_1)}
\]

when the hazard ratio is constant through time.

Assuming that group one is the control group, it may be easiest during the planning stages of a study to find \( S_1 \) and state the minimum value of \( HR \) that would make the experimental treatment useful. The last equation can then be manipulated to calculate a value for \( S_2 \) as follows

\[
S_2 = \exp\left\{HR\left(\log(S_1)\right)\right\}.
\]

Sometimes it is more convenient to state hazard ratio in terms of the median survival times. In this case, the hazard ratio is estimated using

\[
HR = \frac{M_1}{M_2}
\]

when the hazard ratio is constant for different times.
The Logrank Statistic

The following results are excerpted from Reboussin (1992). The logrank statistic is given by the equation

\[
L(d) = \sum_{i=1}^{d} \left( \frac{x_i r_{ic}}{r_{ic} + r_{it}} \right)
\]

where \( d \) is the number of events, \( x_i \) is 1 if the event at time \( t_i \) is in the control group and 0 if it is in the treatment group, \( r_{ic} \) is the number of patients in the control group at risk just before \( t_i \), and \( r_{it} \) is the corresponding number of patients at risk in the treatment group.

If \( r_{ic} \approx r_{it} \) and \( HR \) is close to 1, then the sequential logrank statistic is (approximately)

\[
z_k = 2 \frac{L(d_k)}{d_k}
\]

The subscript \( k \) indicates that the computations use all data that are available at the time of the \( k^{th} \) interim analysis or \( k^{th} \) look (\( k \) goes from 1 to \( K \)).

Spending Functions

Lan and DeMets (1983) introduced alpha spending functions, \( \alpha(\tau) \), that determine a set of boundaries \( b_1, b_2, \ldots, b_K \) for the sequence of test statistics \( z_1, z_2, \ldots, z_K \). These boundaries are the critical values of the sequential hypothesis tests. That is, after each interim test, the trial is continued as long as \( z_k < b_k \). When \( z_k \geq b_k \), the hypothesis of equal means is rejected and the trial is stopped early.

The time argument \( \tau \) either represents the proportion of elapsed time to the maximum duration of the trial or the proportion of the sample that has been collected. When elapsed time is used, it is referred to as calendar time. When time is measured in terms of the sample, it is referred to as information time. Since it is a proportion, \( \tau \) can only vary between zero and one.

Alpha spending functions have the characteristics:

\[
\alpha(0) = 0
\]
\[
\alpha(1) = \alpha
\]

The last characteristic guarantees a fixed \( \alpha \) level when the trial is complete. That is,

\[
\Pr(|z_1| \geq b_1 \text{ or } |z_2| \geq b_2 \text{ or } \cdots \text{ or } |z_K| \geq b_k) = \alpha(\tau)
\]

This methodology is very flexible since neither the times nor the number of analyses must be specified in advance. Only the functional form of \( \alpha(\tau) \) must be specified.
PASS provides five popular spending functions plus the ability to enter and analyze your own boundaries. These are calculated as follows:

1. O’Brien-Fleming \[ 2 - 2\Phi \left( \frac{Z_{\alpha/2}}{\sqrt{T}} \right) \]

2. Pocock \[ \alpha \ln(1 + (e - 1)T) \]

3. Alpha * time \[ \alpha T \]
4. \( \text{Alpha} * \text{time}^{1.5} \) \( \alpha t^{3/2} \)

5. \( \text{Alpha} * \text{time}^{2} \) \( \alpha t^{2} \)

6. User Supplied

A custom set of boundaries may be entered.

The O’Brien-Fleming boundaries are commonly used because they do not significantly increase the overall sample size and because they are conservative early in the trial. Conservative in the sense that the means must be extremely different before statistical significance is indicated. The Pocock boundaries are nearly equal for all times. The Alpha*t boundaries use equal amounts of alpha when the looks are equally spaced. You can enter your own set of boundaries using the User Supplied option.
**Sequential Theory**

A detailed account of the methodology is contained in Lan & DeMets (1983), DeMets & Lan (1984), Lan & Zucker (1993), and DeMets & Lan (1994). A brief summary of the theoretical basis of the method will be presented here.

Group sequential procedures for interim analysis are based on their equivalence to discrete boundary crossing of a Brownian motion process with drift parameter $\theta$. The test statistics $z_k$ follow the multivariate normal distribution with means $\theta \sqrt{\tau_k}$ and, for $j \leq k$, covariances $\sqrt{\tau_k / \tau_j}$. The drift is related to the parameters of the z-test through one of the equations

$$\theta = \frac{\log(HR) d_k}{2} \quad \text{(exponential survival)}$$

or

$$\theta = \frac{|1 - HR| \sqrt{d_k}}{1 + HR} \quad \text{(proportional hazards)}.$$  

These equations may be solved for $d_k$, the required number of events, giving

$$d_k = \frac{4\theta^2}{\log(HR)^2} \quad \text{(exponential survival)}$$

or

$$d_k = \left(\frac{(1 + HR)\theta}{1 - HR}\right)^2 \quad \text{(proportional hazards)}.$$  

In survival analysis, the size of a sample is measured in terms of number of events rather than number of patients because it is probable that many of the patients will be censored—their event times are not known. In order to ensure that the sample size produces the required number of events, it must be inflated by the event rates.

The expected number of events can be computed from the proportion surviving using the equation

$$d_k = \frac{N(1 - S_1) + N(1 - S_2)}{2}$$

where $N$ is the total sample size (assumed to be split evenly between groups). This can be solved for $N$ to give the sample size as

$$N = \frac{2d_k}{2 - S_1 - S_2}.$$  

Hence, the algorithm is as follows:

1. Compute boundary values based on a specified spending function and alpha value.
2. Calculate the drift parameter based on those boundary values and a specified power value.
3. Use the drift parameter and the above equation to calculate the appropriate event size per group $d_k$.
4. Use the event size to compute the appropriate sample size, $N$. 

Procedure Tabs

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains the parameters associated with the z-test such as the survival rates, sample sizes, alpha, and beta.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are $S_1$, $S_2$, $Alpha$, $Beta$, or $N$. Under most situations, you will select either $Beta$ or $N$.

Select $N$ when you want to calculate the sample size needed to achieve a given power and alpha level.

Select $Beta$ when you want to calculate the power of an experiment.

$S_1$ (Proportion Surviving 1)

$S_1$ is the proportion of patients belonging to group 1 (controls) that are expected to survive during the study. Since $S_1$ is a proportion, it must be between zero and one. In many studies, this is the proportion surviving in the regular population with the standard treatment.

You may enter a range of values such as 0.1, 0.2, 0.3 or 0.1 to 0.9 by 0.2.

$S_2$ (Proportion Surviving 2)

$S_2$ is the proportion of patients in the experimental group that survive during the study. This is not necessarily the expected proportion. Rather, you may set it to that proportion that, if achieved, would be of special interest. Values below (or above) this amount would not be of interest. For example, if the standard one-year survival proportion is 0.2 and the new treatment raises this proportion to 0.3 (a 50% increase in the proportion surviving), others may be interested in adopting this new treatment.

Sometimes, researchers wish to state the alternative hypothesis in terms of the hazard ratio, $HR$, rather than the value of $S_2$. Using the fact that

$$HR = \frac{\log(S_2)}{\log(S_1)},$$

An appropriate value for $S_2$ may be calculated from $S_1$ and $HR$ using the equation

$$S_2 = \exp\{HR(\log(S_1))\}.$$
Sometimes it is more convenient to state hazard ratio in terms of the median survival times. In this case, the hazard ratio is estimated using

\[ HR = \frac{M_1}{M_2} \]

and the above equation is used to find \( S_2 \).

Since \( S_2 \) is a proportion, it must remain between zero and one. You may enter a range of values such as 0.1, 0.2, 0.3 or 0.1 to 0.9 by 0.2.

**N (Total Sample Size)**

Enter a value (or range of values) for the total sample size. Each group is assumed to have a sample size of \( N/2 \). You may enter a range of values such as 100 to 1000 by 100.

Note that the sample size is based implicitly on the length of the study since we used the equation

\[ N = \frac{2d_k}{2 - S_1 - S_2} \]

to estimate the necessary sample size.

**Alternative Hypothesis**

Specify whether the test is one-sided or two-sided. When a two-sided hypothesis is selected, the value of alpha is halved. Everything else remains the same.

Note that the accepted procedure is to use Two-Sided unless you can justify using a one-sided test.

**Alpha**

This option specifies one or more values for the probability of a type-I error, alpha. This is also called the significance level or test size. A type-I error occurs when you reject the null hypothesis of equal proportions when in fact the proportions are equal.

Values of alpha must be between zero and one. Often, the value of 0.05 is used for alpha since this value is spread across several interim tests. This means that about one trial in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error that you are willing to take.

**Beta (1-Power)**

This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal proportions when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. Now, 0.10 is more common. You should pick a value that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.
Sequential Tab

The Sequential tab contains the parameters associated with Group Sequential Design such as the type of spending function, the times, and so on.

Number of Looks

This is the number of interim analyses (including the final analysis). For example, a five here means that four interim analyses will be run in addition to the final analysis.

Spending Function

Specify which alpha spending function to use. The most popular is the O'Brien-Fleming boundary that makes early tests very conservative. Select User Specified if you want to enter your own set of boundaries.

Boundary Truncation

You can truncate the boundary values at a specified value. For example, you might decide that no boundaries should be larger than 4.0. If you want to implement a boundary limit, enter the value here.

If you do not want a boundary limit, enter None here.

Times

Enter a list of time values here at which the interim analyses will occur. These values are scaled according to the value of the Max Time option.

For example, suppose a 48-month trial calls for interim analyses at 12, 24, 36, and 48 months. You could set Max Time to 48 and enter 12,24,36,48 here or you could set Max Time to 1.0 and enter 0.25,0.50,0.75,1.00 here.

The number of times entered here must match the value of the Number of Looks.

Equally Spaced

If you are planning to conduct the interim analyses at equally spaced points in time, you can enter Equally Spaced and the program will generate the appropriate time values for you.

Max Time

This is the total running time of the trial. It is used to convert the values in the Times box to fractions. The units (months or years) do not matter, as long as they are consistent with those entered in the Times box.

For example, suppose Max Time = 3 and Times = 1, 2, 3. Interim analyses would be assumed to have occurred at 0.33, 0.67, and 1.00.
Informations
You can weight the interim analyses on the amount of information obtained at each time point rather than on actual calendar time. If you would like to do this, enter the information amounts here. Usually, these values are the sample sizes obtained up to the time of the analysis.
For example, you might enter 50, 76, 103, 150 to indicate that 50 individuals where included in the first interim analysis, 76 in the second, and so on.

Upper and Lower Boundaries
If the Spending Function is set to User Supplied you can enter a set of lower test boundaries, one for each interim analysis. The lower boundaries should be negative and the upper boundaries should be positive. Typical entries are 4,3,3,3,2 and 4,3,2,2,2.

Symmetric
If you only want to enter the upper boundaries and have them copied with a change in sign to the lower boundaries, enter Symmetric for the lower boundaries.

Options Tab
The Options tab controls the convergence of the various iterative algorithms used in the calculations.

Max Iterations 1
Specify the maximum number of iterations to be run before the search for the criterion of interest (Alpha, Beta, etc.) is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank.
Recommended: 500 (or more).

Max Iterations 2
This is the maximum number of iterations used in the Lan-DeMets algorithm during its search routine. We recommend a value of at least 200.

Probability Tolerance
During the calculation of the probabilities associated with a set of boundary values, probabilities less than this are assumed to be zero.
We suggest a value of 0.00000000001.

Power Tolerance
This is the convergence level for the search for the spending function values that achieve a certain power. Once the iteration changes are less than this amount, convergence is assumed. We suggest a value of 0.0000001.
If the search is too time consuming, you might try increasing this value.
**Alpha Tolerance**

This is the convergence level for the search for a given alpha value. Once the changes in the computed alpha value are less than this amount, convergence is assumed and iterations stop. We suggest a value of 0.0001.

This option is only used when you are searching for alpha.

If the search is too time consuming, you may try increasing this value.

**Bnd Axes Tab**

The Bnd Axes tab, short for Boundary Axes tab, allows the axes of the spending function plots to be set separately from those of the power plots. The options are identical to those of the Axes tab.

**Example1 - Finding the Sample Size**

A clinical trial is to be conducted over a two-year period to compare the hazard rate of a new treatment to that of the current treatment. The proportion surviving for two years using the current treatment is 0.3. The health community will be interested in the new treatment if the proportion surviving is increased to 0.45, a 50% increase. So that the sample size requirements for several survival proportions can be compared, it is also of interest to compute the sample size at response rates of 0.30, 0.35, 0.40, and 0.50. Assume the survival times are exponential.

Testing will be done at the 0.05 significance level and the power should be set to 0.10. A total of four tests are going to be performed on the data as they are obtained. The O’Brien-Fleming boundaries will be used.

Find the necessary sample sizes and test boundaries assuming equal sample sizes for each arm and two-sided hypothesis tests.

**Setup**

You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions

Power is the probability of rejecting a false null hypothesis. Power should be close to one.
N is the number of items sampled from each group.
Events is the number of events that must occur in each group.
Alpha is the probability of rejecting a true null hypothesis in at least one of the sequential tests.
Beta is the probability of accepting a false null hypothesis at the conclusion of all tests.
S1 is the proportion surviving in group 1.
S2 is the proportion surviving in group 2.
HR is the hazard ratio. It is calculated using Log(S2)/Log(S1).

Summary Statements

A total sample size of 3378 (split equally between the two groups), or 2280 events, achieves 90% power to detect a hazard rate of 0.8720 when the proportions surviving in each group are 0.3000 and 0.3500 at a significance level (alpha) of 0.050000 using a two-sided log rank test.
These results assume that 4 sequential tests are made using the O'Brien-Fleming spending function to determine the test boundaries and that the survival times are exponential.

This report shows the values of each of the parameters, one scenario per row. Note that 254 events are required when $S_2 = 0.45$. Based on the expected survival proportions, this many events will occur if the overall sample size is 407.

Total Sample Size (N)

This is the estimated sample size that is needed to obtain the necessary number of events.

Total Required Events

This is the number of events (deaths, etc.) that are required to achieve the desired power levels.
Plots Section

The values from the above table are displayed in the chart below. Note that this plot actually occurs further down in the report.

![Chart showing N vs S2 with S1=0.3000 Alpha=0.05 Power=0.90 Surv Test]

This plot shows that an increase in sample size from under 1000 to well over 3000 is necessary when the detectable proportion surviving is reduced from 0.4 to 0.35.

Details Section

| Details when Spending = O'Brien-Fleming, N = 407, d = 254, S1 = 0.3000, S2 = 0.4500 |

| Drift | 3.27466 |

This report shows information about the individual interim tests. One report is generated for each scenario.

Look

These are the sequence numbers of the interim tests.

Time

These are the time points at which the interim tests are conducted. Since the Max Time was set to 2 (for two years), these time values are in years. Hence, the first interim test is at half a year, the second at one year, and so on.

We could have set Max Time to 24 so that the time scale was in months.

Lower and Upper Boundary

These are the test boundaries. If the computed value of the test statistic $z$ is between these values, the trial should continue. Otherwise, the trial can be stopped.

Nominal Alpha

This is the value of alpha for these boundaries if they were used for a single, standalone, test. Hence, this is the significance level that must be found for this look in a standard statistical package that does not adjust for multiple looks.
**Inc Alpha**
This is the amount of alpha that is spent by this interim test. It is close to, but not equal to, the value of alpha that would be achieved if only a single test was conducted. For example, if we lookup the third value, 2.35902, in normal probability tables, we find that this corresponds to a (two-sided) alpha of 0.018323. However, the entry is 0.016248. The difference is due to the correction that must be made for multiple tests.

**Total Alpha**
This is the total amount of alpha that is used up to and including the current test.

**Inc Power**
These are the amounts that are added to the total power at each interim test. They are often called the exit probabilities because they give the probability that significance is found and the trial is stopped, given the alternative hypothesis.

**Total Power**
These are the cumulative power values. They are also the cumulative exit probabilities. That is, they are the probability that the trial is stopped at or before the corresponding time.

**Drift**
This is the value of the Brownian motion drift parameter.

**Boundary Plots**

This plot shows the interim boundaries for each look. This plot shows very dramatically that the results must be extremely significant at early looks, but that they are near the single test boundary (1.96 and -1.96) at the last look.
Example2 - Finding the Power

Continuing the scenario began in Example 1, the researcher wishes to calculate the power of the design at sample sizes 50, 250, 450, 650, and 850. Testing will be done at the 0.01, 0.05, 0.10 significance levels and the overall power will be set to 0.10. Find the power of these sample sizes and test boundaries assuming equal sample sizes per arm and two-sided hypothesis tests.

Proceeding as in Example 1, we decide to translate the mean and standard deviation into a percent of mean scale.

Setup
You can enter these values yourself or load the Example 2 template from the Template tab.

</tr>
</tbody>
</table>

These data show the power for various sample sizes and alphas. It is interesting to note that once the sample size is greater than about 450, the value of alpha has comparatively little difference on the value of power.
Example3 - Effect of Number of Looks

Continuing with examples one and two, it is interesting to determine the impact of the number of looks on power. \textit{PASS} allows only one value for the Number of Looks parameter per run, so it will be necessary to run several analyses. To conduct this study, set alpha to 0.05, \( N \) to 407, and leave the other parameters as before. Run the analysis with Number of Looks equal to 1, 2, 3, 4, 6, 8, 10, and 20. Record the power for each run.

**Setup**

You can enter these values yourself or load the Example3 template from the Template tab.

</tbody>
</table>

This analysis shows how little the number of looks impacts the power of the design. The power of a study with no interim looks is 0.905693. When twenty interim looks are made, the power falls to 0.893398—a very small change.
Example4 - Studying a Boundary Set

Continuing with the previous examples, suppose that you are presented with a set of boundaries and want to find the quality of the design (as measured by alpha and power). This is easy to do with PASS. Suppose that the analysis is to be run with five interim looks at equally spaced time points. The upper boundaries to be studied are 3.5, 3.5, 3.0, 2.5, 2.0. The lower boundaries are symmetric. The analysis would be run as follows.

Setup

You can enter these values yourself or load the Example4 template from the Template tab.

Drift: 3.27466

The power for this design is about 0.90. This value depends on both the boundaries and the sample size. The alpha level is about 0.048. This value only depends on the boundaries.
Example5 - Validation using O’Brien-Fleming Boundaries

Reboussin (1992) presents an example for binomial distributed data for a design with two-sided O’Brien-Fleming boundaries, looks = 3, alpha = 0.05, beta = 0.10, S1 = 0.30, S2 = 0.786 (which gives a hazard ratio of 0.20). They compute a drift of 3.261 and the number of events at 16.42. The upper boundaries are: 4.8769, 3.3569, 2.6803, 2.2898, 2.0310.

To test that PASS provides the same result, enter the following.

The number of events, rounded to 17, matches the 16.42 reported in Reboussin (1992).
Chapter 800

Correlation Coefficient

Introduction

The correlation coefficient, $\rho$ (rho), is a popular statistic for describing the strength of the relationship between two variables. The correlation coefficient is the slope of the regression line between two variables when both variables have been standardized by subtracting their means and dividing by their standard deviations. The correlation ranges between plus and minus one.

When $\rho$ is used as a descriptive statistic, no special distributional assumptions need to be made about the variables (Y and X) from which it is calculated. When hypothesis tests are made, you assume that the observations are independent and that the variables are distributed according to the bivariate-normal density function. However, as with the t-test, tests based on the correlation coefficient are robust to moderate departures from this normality assumption.

The population correlation $\rho$ is estimated by the sample correlation coefficient $r$. Note we use the symbol $R$ on the screens and printouts to represent the population correlation.

Difference between Linear Regression and Correlation

The correlation coefficient is used when both X and Y are from the normal distribution (in fact, the assumption actually is that X and Y follow a bivariate normal distribution). The point is, X is assumed to be a random variable whose distribution is normal. In the linear regression context, no statement is made about the distribution of X. In fact, X is not even a random variable. Instead, it is a set of fixed values such as 10, 20, 30 or -1, 0, 1. Because of this difference in definition, we have included both Linear Regression and Correlation algorithms. This module deals with the Correlation (random X) case.

Test Procedure

The testing procedure is as follows. $H_0$ is the null hypothesis that the true correlation is a specific value, $\rho_0$ (usually, $\rho_0 = 0$). $H_A$ represents the alternative hypothesis that the actual correlation of the population is $\rho_1$, which is not equal to $\rho_0$. Choose a value $R_\alpha$, based on the distribution of the sample correlation coefficient, so that the probability of rejecting $H_0$ when $H_0$ is true is equal to a specified value, $\alpha$. Select a sample of $n$ items from the population and compute the sample correlation coefficient, $r_S$. If $r_S > R_\alpha$, reject the null hypothesis that $\rho = \rho_0$ in favor of an alternative hypothesis that $\rho = \rho_1$, where $\rho_1 > \rho_0$. The power is the probability of rejecting $H_0$ when the true correlation is $\rho_1$. 
All calculations are based on the algorithm described by Guenther (1977) for calculating the cumulative correlation coefficient distribution.

**Calculating the Power**

Let $R(r|N,\rho)$ represent the area under a correlation density curve to the left of $r$. $N$ is the sample size and $\rho$ is the population correlation. The power of the significance test of $\rho_1 > \rho_0$ is calculated as follows:

1. Find $r_{\alpha}$ such that $1 - R(r_{\alpha}|N,\rho_0) = \alpha$.
2. Compute the power $= 1 - R(r_{\alpha}|N,\rho_1)$.

Notice that the calculations follow the same pattern as for the t-test. First find the rejection region by finding the critical value ($r_{\alpha}$) under the null hypothesis. Next, calculate the probability that a sample of size $N$ drawn from the population defined by setting the correlation to $\rho_1$ is in this rejection region. This is the power.

**Procedure Options**

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

**Data Tab**

The Data tab contains most of the parameters and options that you will be concerned with.

**Find**

This option specifies the parameter to be calculated from the values of the other parameters. Under most conditions, you would either select Beta or $N$.

Select $N$ when you want to determine the sample size needed to achieve a given power and alpha error level.

Select Beta when you want to calculate the power.

**R0 (Baseline Correlation)**

Specify the value of $\rho_0$. Note that the range of the correlation is between plus and minus one. This value is usually set to zero.
R1 (Alternative Correlation)
Specify the value of $\rho_1$, the population correlation under the alternative hypothesis. Note that the range of the correlation is between plus and minus one. The difference between $R_0$ and $R_1$ is being tested by this significance test.

You can enter a range of values separated by blanks or commas.

N (Sample Size)
The number of observations in the sample. Each observation is made up of two values: one for $X$ and one for $Y$.

Alternative Hypothesis
This option specifies the alternative hypothesis. This implicitly specifies the direction of the hypothesis test. The null hypothesis is $H_0: \rho_0 = \rho_1$.

Note that the alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:
- **Ha: $R_0 \not< R_1$**. This is the most common selection. It yields the two-tailed test. Use this option when you are testing whether the correlation values are different, but you do not want to specify beforehand which correlation is larger.
- **Ha: $R_0 < R_1$**. This option yields a one-tailed test.
- **Ha: $R_0 > R_1$**. This option also yields a one-tailed test.

Alpha (Significance Level)
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal correlations when in fact they are equal.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal correlations when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
Example 1 - Finding the Power

Suppose a study will be run to test whether the correlation between forced vital capacity (X) and forced expiratory value (Y) in a particular population is 0.30. Find the power when alpha is 0.01, 0.05, and 0.10 and the N = 20, 60, 100.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

Report Definitions

Power is the probability of rejecting a false null hypothesis. It should be close to one.

N is the size of the sample drawn from the population. To conserve resources, it should be small.

Alpha is the probability of rejecting a true null hypothesis. It should be small.

Beta is the probability of accepting a false null hypothesis. It should be small.

R0 is the value of the population correlation under the null hypothesis.

R1 is the value of the population correlation under the alternative hypothesis.

Summary Statements

A sample size of 20 achieves 9% power to detect a difference of -0.30000 between the null hypothesis correlation of 0.00000 and the alternative hypothesis correlation of 0.30000 using a two-sided hypothesis test with a significance level of 0.01000.

This report shows the values of each of the parameters, one scenario per row. The values from this table are plotted in the chart below.

Plots Section

This plot shows the relationship between alpha and power in this example.
Example 2 - Finding the Sample Size

Continuing with the last example, find the sample size necessary to achieve a power of 90% with a 0.05 significance level.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

Chapter 805

Two Correlations

Introduction

The correlation coefficient (or correlation), $\rho$, is a popular parameter for describing the strength of the association between two variables. The correlation coefficient is the slope of the regression line between two variables when both variables have been standardized. It ranges between plus and minus one. This chapter covers the case in which you want to test the difference between two correlations, each coming from a separate sample.

Since the correlation is the standardized slope between two variables, you could also apply this procedure to the case in which you want to test whether the slopes in two groups are equal.

Test Procedure

In the following discussion, $\rho$ is the population correlation coefficient and $r$ is the value calculated from a sample. The testing procedure is as follows. $H_0$ is the null hypothesis that $\rho_1 = \rho_2$. $H_A$ represents the alternative hypothesis that $\rho_1 \neq \rho_2$ (one-tailed hypotheses are also available). To construct the hypothesis test, transform the correlations using the Fisher-z transformation.

$$ z_i = \frac{1}{2} \log \left( \frac{1 + r_i}{1 - r_i} \right) $$

$$ Z_i = \frac{1}{2} \log \left( \frac{1 + \rho_i}{1 - \rho_i} \right) $$

This transformation is used because the combined distribution of $r_1$ and $r_2$ is too difficult to work with, but the distributions of $z_1$ and $z_2$ are approximately normal.

Note that the reverse transformation is

$$ r_i = \frac{e^{z_i} - e^{-z_i}}{e^{z_i} + e^{-z_i}} $$

Once the correlations have been converted into $z$ values, the normal distribution may be used to conduct the test of $Z_1 - Z_2$. The standard deviation of the difference is given by

$$ \sigma_{z_1 - z_2} = \sqrt{\frac{1}{N_1 - 3} + \frac{1}{N_2 - 3}} $$
The test statistic is given by

\[ z = \frac{(z_1 - z_2) - (Z_1 - Z_2)}{\sigma_{z_1 - z_2}} \]

Note that the lower case \( z \)'s represent the values calculated from the two samples and the upper case \( Z \)'s represent the hypothesized population values.

**Calculating the Power**

1. Find \( z_\alpha \) such that \( 1 - \Phi(z_\alpha) = \alpha \), where \( \Phi(x) \) is the area under the standardized normal curve to the left of \( x \).

2. Calculate: 
\[
Z_1 = \frac{1}{2} \log \left( \frac{1 + \rho_1}{1 - \rho_1} \right)
\]

3. Calculate: 
\[
Z_2 = \frac{1}{2} \log \left( \frac{1 + \rho_2}{1 - \rho_2} \right)
\]

4. Calculate: 
\[
\sigma_{z_1 - z_2} = \sqrt{\frac{1}{N_1 - 3} + \frac{1}{N_2 - 3}}
\]

5. Calculate: 
\[
x_\alpha = Z_1 + Z_2 + z_\alpha \sigma_{z_1 - z_2}
\]

6. Calculate: 
\[
z_\alpha = \frac{x_\alpha}{\sigma_{z_1 - z_2}}
\]

7. Calculate: 
\[
\text{Power} = 1 - \Phi(z_\alpha)
\]
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are $R_1$, $R_2$, $N_1$, $N_2$, $\alpha$, and $\beta$. Under most situations, you will select either $\beta$ or $N_1$.

Select $N_1$ when you want to calculate the sample size needed to achieve a given power and alpha level.

Select $\beta$ when you want to calculate the power of an experiment.

R1 (Correlation Group 1)

Specify the value of the population correlation coefficient of group one. Possible values range between plus and minus one.

You can enter a single value or a range of values separated by commas or blanks.

Note that the power depends on the specific values of $R_1$ and $R_2$, not just their difference. Hence, $R_1 = 0$ and $R_2 = 0.3$ will have a different power from $R_1 = 0.3$ and $R_2 = 0.6$.

R2 (Correlation Group 2)

Specify the value of the population correlation coefficient from group two under the alternative hypothesis. Possible values range between plus and minus one.

You can enter a single value or a range of values separated by commas or blanks.

Alpha (Significance Level)

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal correlations when in fact they are equal.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.
Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal correlations when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.

Alternative Hypothesis
This option specifies the alternative hypothesis. This implicitly specifies the direction of the hypothesis test. The null hypothesis is always $H_0: \rho_1 = \rho_2$.

Possible selections are:

Ha: $R_1 \leq R_2$. This is the most common selection. It yields the two-tailed test. Use this option when you are testing whether the correlation values are different, but you do not want to specify beforehand which value is larger.

Ha: $R_1 < R_2$. This option yields a one-tailed test. When you use this option, you should be careful to enter values for $R_1$ and $R_2$ that follow this relationship.

Ha: $R_1 > R_2$. This option yields a one-tailed test. When you use this option, you should be careful to enter values for $R_1$ and $R_2$ that follow this relationship.

N1 (Sample Size Group 1)
Enter a value (or range of values) for the sample size of this group. Note that these values are ignored when you are solving for $N1$. You may enter a range of values such as 10 to 100 by 10.

N2 (Sample Size Group 2)
Enter a value (or range of values) for the sample size of group 2 or enter Use R to base N2 on the value of N1. You may enter a range of values such as 10 to 100 by 10.

Use R
When Use R is entered here, $N2$ is calculated using the formula

$$N2 = \lceil R \cdot N1 \rceil$$

where $R$ is the Sample Allocation Ratio and $\lceil Y \rceil$ is the first integer greater than or equal to $Y$. For example, if you want $N1 = N2$, select Use R and set $R = 1$.

R (Sample Allocation Ratio)
Enter a value (or range of values) for $R$, the allocation ratio between samples. This value is only used when $N2$ is set to Use R.

When used, $N2$ is calculated from $N1$ using the formula: $N2 = \lceil R \cdot N1 \rceil$ where $\lceil Y \rceil$ is the next integer greater than or equal to $Y$. Note that setting $R = 1.0$ forces $N2 = N1$. 
Example 1 - Finding the Power

A researcher wants to compare the relationship between weight and heart rate in males and females. If the correlation between weight and heart rate is 0.3 in a sample of 100 males and 0.5 in a sample of 100 females, what is the power of a two sided test for the difference between correlations at the 0.01 and 0.05 significance levels? Also compute the power for samples of 20, 200, 300, 400, and 600.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

**Report Definitions**

Power is the probability of rejecting a false null hypothesis. It should be close to one.
N1 and N2 are the sizes of the samples drawn from the two populations. To conserve resources, it should be small.
Allocation Ratio is N1/N2 so that N2 = N1 x R.
Alpha is the probability of rejecting a true null hypothesis. It should be small.
Beta is the probability of accepting a false null hypothesis. It should be small.
R1 is the value of both correlations under the null hypothesis.
R2 is the correlation in group two under the alternative hypothesis.

**Summary Statements**

Group sample sizes of 20 and 20 achieve 3% power to detect a difference of 0.20000 between the null hypothesis that both group correlations are 0.30000 and the alternative hypothesis that the correlation in group 2 is 0.50000 using a two-sided z test (which uses Fisher's z-transformation) with a significance level of 0.01000.

This report shows the values of each of the parameters, one scenario per row. The definitions of each column are given in the Report Definitions section of the report, so they will not be repeated here.

The values from this table are plotted in the chart below.

**Plots Section**

![Plot](plot.png)

This plot shows the relationship between alpha, power, and sample size in this example.
Example 2 - Finding the Sample Size

Continuing with the previous example, suppose the researchers want to determine the exact sample size necessary to achieve 90% power at a 0.05 significance level.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

PASS has also calculated the power to be 22%.
Chapter 810

Intraclass Correlation

Introduction

The intraclass correlation coefficient is often used as an index of reliability in a measurement study. In these studies, there are \( N \) observations made on each of \( K \) individuals. These individuals represent a factor observed at random. This design arises when \( K \) subjects are each rated by \( N \) raters.

The intraclass correlation coefficient may be thought of as the correlation between any two observations made on the same subject. When this correlation is high, the observations on a subject tend to match, and the measurement reliability is ‘high.’

Technical Details

Our formulation comes from Walter, Eliasziw, and Donner (1998) and Winer (1991). Denote response \( j \) of subject \( i \) by \( Y_{ij} \), where \( i = 1, 2, \ldots, K \) and \( j = 1, 2, \ldots, N \). The model for this situation is

\[
Y_{ij} = \mu + a_i + e_{ij}
\]

where the random subject effects \( a_i \) are normally distributed with mean 0 and variance \( \sigma_a^2 \) and the measurement errors, \( e_{ij} \) are normally distributed with mean 0 and variance \( \sigma_e^2 \). We assume that the subject effects and the measurement errors are independent. The intraclass correlation is then defined as

\[
\rho = \frac{\sigma_a^2}{\sigma_a^2 + \sigma_e^2}
\]

The hypothesis test is stated formally as

\[
H_0: \rho = \rho_0 \\
H_1: \rho = \rho_1 > \rho_0
\]
This hypothesis is tested from the data of a one-way analysis of variance table using the value: 
\( \frac{MS_a}{MS_e} \). The critical value for the test statistic is 
\[
C\left(F_{1-\alpha/2, df1, df2}\right)
\]
where
\[
C = 1 + \left[ \frac{N\rho_0}{1 - \rho_0} \right]
\]
\[
df1 = K - 1
\]
\[
df2 = K(N - 1)
\]
The power of this test procedure is given by
\[
Power = 1 - P(F \geq C_0 F_{1-\alpha/2, df1, df2})
\]
where
\[
C_0 = \frac{1 + N\rho_0 / (1 - \rho_0)}{1 + N\rho_1 / (1 - \rho_1)}
\]

**Procedure Options**

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

**Data Tab**

The Data tab contains most of the parameters and options that you will be concerned with.

**Find**

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are \( R0, R1, K, N, \) Alpha, and Beta (or Power).

Under most situations, you will select either Beta to calculate power or \( N \) to calculate sample size.

Note that the value selected here always appears as the vertical axis on the charts.

The program is set up to evaluate beta directly. For the other parameters, a search is made using an iterative procedure until an appropriate value is found.
Alpha (Significance Level)
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

Values between 0.001 and 0.100 are acceptable. The value of 0.05 has become the standard. This means that about one test in twenty will falsely reject the null hypothesis. Although 0.05 is the standard value, you should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Note that you can enter a range of values such as 0.01, 0.05 or 0.01 to 0.05 by 0.01.

Beta (1-Power)
This option specifies one or more values for beta (the probability of accepting a false null hypothesis). Since statistical power is equal to one minus beta, specifying beta implicitly specifies the power. For example, setting beta at 0.20 also sets the power to 0.80.

Values must be between zero and one. The value of 0.20 has often used for beta. However, you should pick a value for beta that represents the risk of this type of error you are willing to take.

Note that you can enter a range of values such as 0.10, 0.20 or 0.05 to 0.20 by 0.05.

If your only interest is in determining the appropriate sample size for a confidence interval, set beta to 0.5.

R0 (Intraclass Correlation 0)
This is the value(s) of the intraclass correlation coefficient when the null hypothesis is true. You may enter a single value or a list of values. The range of R0 is between zero and R1.

The intraclass correlation is calculated as \( V(A)/(V(A)+V(E)) \) where \( V(E) \) is the variation within a subject and \( V(A) \) is the variation between subjects. It is a measure of the extent to which the observations within a subject are similar (or dependent) relative to observations from other subjects.

R1 (Intraclass Correlation 1)
This is the value(s) of the intraclass correlation coefficient when the alternative hypothesis is true. You may enter a single value or a list of values. The range of R1 is between R0 and one.

K (Number of Subjects)
Enter a value (or range of values) for the number of subjects, K, that are measured.

You may enter a range of values such as 50, 150, 250 or 50 to 300 by 50.

N (Observations Per Subject)
Enter a value (or range of values) for the number of observations, N, per subjects. In a reliability study, this is the number of raters (assuming each subject is rated by all raters).

You may enter a range of values such as 2, 3, 4 or 2 to 12 by 2.
Options Tab
This tab sets a couple of options used in the iterative procedures.

Maximum Iterations
Specify the maximum number of iterations allowed before the search for the criterion of interest is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank. A value of 500 is recommended.

Example1 - Calculating Power

Suppose that a study is to be conducted in which $R_0 = 0.2; R_1 = 0.3; K = 50$ to 250 by 100; Alpha = 0.05; and $N = 2$ to 5 by 1 and beta is to be calculated.

Setup
You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions
Power is the probability of rejecting a false null hypothesis. It should be close to one.
K is the number of subjects.
N is the number of observations per subject in the sample.
R0 is intraclass correlation assuming the null hypothesis.
R1 is intraclass correlation assuming the alternative hypothesis.
Alpha is the probability of rejecting a true null hypothesis. It should be small.
Beta is the probability of accepting a false null hypothesis. It should be small.

Summary Statements
A sample size of 50 subjects with 2 observations per subject achieves 18% power to detect an intraclass correlation of 0.300 under the alternative hypothesis when the intraclass correlation under the null hypothesis is 0.200 using an F-test with a significance level of 0.05000.

This report shows the power for each of the scenarios.

Plot Section

This plot shows the relation between power, number of subjects (K), and observations per subject (N).
Example2 - Validation using Walter

Walter et al. (1998) page 106 give a table of sample sizes. When R0 is 0.2, R1 is 0.3, K is 544, N is 2, and Alpha is 0.05, Beta is 0.80.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

PASS has also calculated the power as 0.80.
Chapter 815

Coefficient Alpha: One Set

Introduction

Coefficient alpha, or Cronbach’s alpha, is a measure of the reliability of a scale consisting of \( k \) parts. The \( k \) parts usually often represent \( k \) items on a questionnaire or \( k \) raters. This module calculates power and sample size for testing whether coefficient alpha, \( \rho \), is different from a given value such as zero.

Technical Details

Feldt et al. (1987) has shown that if \( \hat{\rho} \) is the estimated value of coefficient alpha computed from a sample of size \( N \) questionnaires with \( k \) items, the statistic \( W \) is distributed as an \( F \) ratio with degrees of freedom \( N-1 \) and \( (k-1)(N-1) \), where

\[
W = \frac{1-\rho_0}{1-\hat{\rho}}
\]

and \( \rho_0 \) is the value of \( \rho \) assumed by the null hypothesis, \( H_0 \).

Calculating the Power

Using the above definition of \( W \), the power of the significance test of \( \rho > \rho_0 \) is calculated as follows:

1. Find \( F_\alpha \) such that \( \text{Prob}(F_{1-\alpha,N-1,(k-1)(N-1)}) = 1 - \alpha \)

2. Compute \( \rho_c = \frac{F_\alpha + \rho_0 - 1}{F_\alpha} \)

3. Compute \( W_1 = \frac{1-\rho_c}{1-\rho} \), where \( \rho_1 \) is the value of \( \rho \) at which the power is calculated.

4. Compute the power = \( 1 - \text{Pr}(W_1 > F_{N-1,(k-1)(N-1)}) \)
**Procedure Options**

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

**Data Tab**

The Data tab contains most of the parameters and options that you will be concerned with.

**Find**

This option specifies the parameter to be calculated from the values of the other parameters. Under most conditions, you would either select *Beta* or *N*.

Select *N* when you want to determine the sample size needed to achieve a given power and alpha error level.

Select *Beta* when you want to calculate the power of an experiment.

**CA0 (Coefficient Alpha|H0)**

Specify the value of $\rho_0$, the value of coefficient alpha under the null hypothesis. Usually, this value will be zero, but any value between -1 and 1 is valid as long as it is not equal to CA1.

You may enter a list of values separated by blanks such as 0 0.1 0.2.

**CA1 (Coefficient Alpha|H1)**

Specify the value of $\rho_1$, the value of coefficient alpha at which the power is computed. Usually, this value is positive, but any value between -1 and 1 is valid as long as it is not equal to CA0.

You may enter a list of values separated by blanks such as 0.1 0.2 0.3.

**N (Sample Size)**

Specify the number of observations in the sample. You may enter a range such as 10 to 100 by 10 or a list of values separated by commas or blanks such as 20 50 100.

**K (Number of Items or Raters)**

K is the number of items or raters in the study. Since it is a count, it must be an integer greater than one. You may enter a list of values separated by blanks.
Alternative Hypothesis

This option specifies whether the alternative hypothesis is one-sided or two-sided. It also specifies the direction of the hypothesis test. The null hypothesis is $H_0: \rho = \rho$. The alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- **H1: CA0 <> CA1.** This is the most common selection. It yields the two-tailed test. Use this option when you are testing whether values are different, but you do not want to specify beforehand which is larger.

- **H1: CA0 < CA1.** This option yields a one-tailed test.

- **H1: CA0 > CA1.** This option also yields a one-tailed test.

Alpha (Significance Level)

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when it is true.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta (1 - Power)

This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject a false null hypothesis.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
Example1 - Finding the Power

Suppose a study is being designed to test whether the coefficient alpha is 0.6 against the two-sided alternative. Find the power when $K = 20$, alpha = 0.05, CA1 = 0.65 0.70 0.75, and $N = 50\ 100\ 200\ 300\ 500\ 700\ 1000\ 1400$.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

### Report Definitions

- **Power** is the probability of rejecting a false null hypothesis.
- **N** is the total sample size.
- **K** is the number of items or raters.
- **CA1** is the value of coefficient alpha at which the power is computed.
- **CA0** is the value of coefficient alpha under the null hypothesis.
- **Alpha** is the probability of rejecting a true null hypothesis. It should be small.
- **Beta** is the probability of accepting a false null hypothesis. It should be small.
- **H0** is the null hypothesis that coefficient alpha equals CA0.
- **H1** is the alternative hypothesis that coefficient alpha does not equal CA0.

### Summary Statements

A sample of 50 subjects each responding to 20 items achieves 11% power to detect the difference between the coefficient alpha under the null hypothesis of 0.60000 and the coefficient alpha under the alternative hypothesis of 0.65000 using a two-sided F-test with a significance level of 0.05000.

This report shows the values of each of the parameters, one scenario per row. The values from this table are plotted in the chart below.

## Plots Section

This plot shows the relationship between CA1, N, and power.
Example2 - Finding the Sample Size

Continuing with the last example, find the sample size necessary to achieve a power of 90% with a 0.05 significance level.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

Chapter 820

Coefficient Alpha: Two Sets

Introduction

Coefficient alpha, or Cronbach’s alpha, is a popular measure of the reliability of a scale consisting of $k$ parts. The $k$ parts often represent $k$ items on a questionnaire (scale) or $k$ raters. This module calculates power and sample size for testing whether two coefficient alphas are different when the two samples are either dependent or independent.

Technical Details

Feldt et al. (1999) presents methods for testing one-, or two-, sided hypotheses about two coefficient alphas, which we label $\rho_1$ and $\rho_2$. The results assume that $N_i$ observations for each of $k_i$ items are available for one scale and $N_2$ observations for each of $k_2$ items are available for another scale. These sets of observations may either be from two independent groups of subjects (independent case) or two sets of observations on each subject (dependent case). In the dependent case, $N_1 = N_2$ and the correlation coefficient between the overall scores of each scale is represented by $\phi$. For the independent case $\phi = 0$.

Suppose $\hat{\rho}_1$ and $\hat{\rho}_2$ are the sample estimates of $\rho_1$ and $\rho_2$, respectively. Hypothesis tests are based on the result that the test statistic,

$$
W = \left( \frac{1 - \hat{\rho}_2}{1 - \hat{\rho}_1} \right) \left( \frac{1 - \rho_1}{1 - \rho_2} \right),
$$

is approximately distributed as a central $F$ variable with degrees of freedom $\nu_1$ and $\nu_2$. The values of $\nu_i$ and $\nu_2$ depend on $N_i$, $N_2$, $k_1$, $k_2$, and $\phi$.

Also define

$$
c_i = (N_i - 1)(k_i - 1), \quad i = 1, 2
$$
Independent Case
When the two scales are independent, there are two situations that must be considered separately.
If \( c_i > 1000 \) and \( k_i > 25 \), the values of \( \nu_1 \) and \( \nu_2 \) are computed using
\[
\nu_1 = N_1 - 1 \\
\nu_2 = N_2 - 1
\]
otherwise, they are computed using
\[
\nu_1 = \frac{2A^2}{2B - AB - A^2} \\
\nu_2 = \frac{2A}{A - 1}
\]
where
\[
A = \frac{c_i(N_2 - 1)}{(c_i - 2)(N_2 - 3)} \\
B = \frac{(N_1 + 1)(N_2 - 1)(c_2 + 2)c_1^2}{(N_2 - 3)(N_2 - 5)(N_1 - 1)(c_i - 2)(c_i - 4)c_2}
\]

Dependent Case
When the two scales are dependent, it follows that \( N_1 = N_2 = N \). There are two situations that must be considered separately.
If \( c_i > 1000 \) and \( k_i > 25 \), the values of \( \nu_1 \) and \( \nu_2 \) are computed using
\[
\nu_1 = \nu_2 = \frac{N - 1 - 7\phi^2}{1 - \phi^2}
\]
otherwise, they are computed using
\[
\nu_1 = \frac{2M^2}{V(2 - M) - M^2(M - 1)} \\
\nu_2 = \frac{2M}{M - 1}
\]
where
\[
M = A - \frac{2\phi^2}{N - 1} \\
V = B - A^2 - \frac{4\phi^2}{N - 1}
\]
Calculating the Power

Let $\rho_{20}$ be the value of coefficient alpha in the second set under $H_0$, $\rho_{21}$ be the value of coefficient alpha in the second set at which the power is calculated, and $\rho_1$ be the value of coefficient alpha in the first set. The power of the one-sided hypothesis that $H_0: \rho_{20} \leq \rho_1$ versus the alternative that $H_1: \rho_{20} > \rho_1$ is calculated as follows:

1. Find $F_\alpha$ such that $\text{Prob}(F < F_{\alpha, v_1, v_2}) = \alpha$

2. Compute $\delta' = \frac{1 - \rho_1}{F_\alpha \left(1 - \rho_{20}\right)}$

3. Compute $W_1 = \left(\frac{1 - \rho_1}{1 - \rho_{21}}\right) \delta'$

4. Compute the power $= 1 - \text{Pr}(W_1 > F_{v_1, v_2})$
Procedure Options
This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab
The Data tab contains most of the parameters and options of interest for this procedure.

Find
This option specifies the parameter to be calculated from the values of the other parameters. Under most conditions, you would either select Beta or N1.
Select N1 when you want to determine the sample size needed to achieve a given power and alpha error level.
Select Beta when you want to calculate the power of an experiment.

CA1 (Coefficient Alpha Set 1)
Specify the value of $\rho_1$, the value of coefficient alpha, for dataset one. Often, this value will be zero, but any value between -1 and 1 is valid as long as it is not equal to CA21.
You may enter a list of values separated with blanks or a range of values.

CA20 (Coefficient Alpha Set 2|H0)
Enter the value of coefficient alpha in dataset two under the null hypothesis. The null hypothesis is H0: CA1=CA20, so often you will set this value equal to CA1. Any value between -1 and 1 (non-inclusive) is valid as long as it is not equal to CA21.
You may enter CA1 to indicate that you want the value of CA1 copied here. You may also enter a multiple of CA1 such as 1.5CA1.
You may enter a list of values separated with blanks or a range of values.

CA21 (Coefficient Alpha Set 2|H1)
Enter the value of coefficient alpha in dataset two at which the power is computed. Any value between -1 and 1 (non-inclusive) is valid as long as it is not equal to CA20. The values of CA20 and CA21 should match the direction set by the ‘Alternative Hypothesis’ option.
You may enter a list of values separated with blanks or a range of values.
**Phi (Correlation Between Sets)**

This option implicitly specifies the two datasets as being either independent (datasets on different subjects) or dependent (both datasets on the same subjects). Suppose you calculate the average score for each subject for both dataset one and dataset two. This parameter is the correlation between those two averages over all subjects. If the correlation is zero, the two datasets are assumed to be independent. That is, it is assumed that they come from different sets of subjects.

If the correlation is non-zero, the two datasets are assumed to be dependent. That is, it is assumed that both sets of items were measured on the same subjects. Typical values in this case are between 0.2 and 0.7. When the datasets are dependent, it is assumed that $N_1 = N_2$.

Since this is a correlation, the theoretical range is from -1 to 1. Typical values are 0.0 for independent designs and between 0.2 and 0.7 for dependent designs.

**K1 (Items/Scale in Set 1)**

K1 is the number of items or raters in dataset one. Since it is a count, it must be an integer. K1 must be greater than or equal to two.

You may enter a list of values separated with blanks or a range of values.

**N1 (Sample Size in Set 1)**

N1 is the sample size (number of observations or subjects) in dataset one. Feldt (1999) states that it is ill-advised to use sample sizes less than 30.

You may enter a list of values separated with blanks or a range of values.

**K2 (Items/Scale in Set 2)**

K2 is the number of items or raters in dataset two. Since it is a count, it must be an integer greater than or equal to two.

You may enter a list of values separated with blanks or a range of values.

For ease of input, you can enter multiples of K1. For example, all of the following entries are allowed:

$$K1 \ 2K1 \ 0.5K1$$

**N2 (Sample Size in Set 2)**

N2 is the sample size (number of observations or subjects) in dataset two. Feldt (1999) states that it is ill-advised to use sample sizes less than 30. Note that if phi is non-zero, this value will be forced equal to $N_1$ regardless of what is entered here.

For ease of input, when phi is non-zero, you can enter multiples of N1. For example, all of the following entries are allowed:

$$N1 \ 2N1 \ 0.5N1$$

You may enter a list of values separated with blanks or a range of values.
**Alternative Hypothesis**
This option specifies whether the alternative hypothesis is one-sided or two-sided. It also specifies the direction of the hypothesis test. The null hypothesis is $H_0: \rho_1 = \rho_2$. The alternative hypothesis enters into power calculations by specifying the rejection region of the hypothesis test. Its accuracy is critical.

Possible selections are:

- **H1: CA1 <> CA2.** This is the most common selection. It yields the *two-tailed* test. Use this option when you are testing whether values are different, but you do not want to specify beforehand which is larger.
- **H1: CA1 < CA2.** This option yields a *one-tailed* test.
- **H1: CA1 > CA2.** This option also yields a *one-tailed* test.

**Alpha (Significance Level)**
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

**Beta (1 - Power)**
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equality when it is false.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
Example1 - Finding the Power

Suppose a study is being designed to compare the coefficient alphas of two scales. The researchers are going to use a two-sided F-test at a significance level of 0.05. Past experience has shown that CA1 is approximately 0.4. The researchers will use different subjects in each dataset. Find the power when K1 = K2 = 10, CA20 = CA1, N1 = 50, 100, 150, 200, 250, and 300, N2 = N1, and CA21 = 0.6 and 0.7.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

Option | Value
--- | ---
Data Tab | Beta and Power
Find | .05
CA1 | 0.4
CA20 | CA1
CA21 | 0.60 0.70
K1 | 10
N1 | 50 to 300 by 50
K2 | K1
N2 | N1
Alternative Hypothesis | .05
H1: CA1 <> CA2
Phi | 0
Alpha | 0.05
Beta | Ignored since this is the Find setting

Report Definitions
H0, H1 abbreviate the null and alternative hypotheses, respectively.
Power is the probability of rejecting H0 when it is false. It should be close to one.
N1 & N2 are the sample sizes of datasets one and two, respectively.
K1 & K2 are the number of items in datasets one and two, respectively.
CA21 is the coefficient alpha in dataset two at which the power is calculated.
CA20 is the coefficient alpha in dataset two under H0.
CA1 is the coefficient alpha in dataset one.
Phi is the correlation between the average scores of each of the two datasets.
Alpha is the probability of a type-I error: rejecting H0 when it is true.
Beta is the probability of a type-II error: accepting H0 when it is false. Power = 1 - Beta.

Summary Statements
Samples of 10 items on 50 subjects in dataset one and 10 items on 50 subjects in dataset two achieve 26% power to detect the difference between the coefficient alphas in the two datasets.
Under the null hypothesis, the coefficient alphas in datasets one and two are 0.4000 and 0.4000, respectively. The power is computed assuming that the coefficient alpha of dataset two is actually 0.6000. The test statistic used is the two-sided F-test. The significance level of the test was 0.0500.

This report shows the values of each of the parameters, one scenario per row. The values from this table are plotted in the chart below.

Plots Section

This plot shows the relationship between CA21, N1, and power.
Example2 - Finding the Sample Size

Continuing with the last example, find the sample size necessary to achieve a power of 90% at the 0.05 significance level.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example2 by clicking the Template tab and loading this template.

Note that PASS’s result is slightly different from Feldt’s because PASS uses fractional degrees of freedom and Feldt rounds to the closest integer. Although the difference in power is small, allowing fractional degrees of freedom is more accurate.
Chapter 850

Cox Proportional Hazards Regression

Cox proportional hazards regression models the relationship between the hazard function $\lambda(t \mid X)$ of survival time and $k$ covariates using the following formula

$$\log \left( \frac{\lambda(t \mid X)}{\lambda_0(t)} \right) = \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k$$

where $\lambda_0(t)$ is the baseline hazard. Note that the covariates may be discrete or continuous.

This procedure calculates power and sample size for testing the hypothesis that $\beta_1 = 0$ versus the alternative that $\beta_1 = B$. Note that $\beta_1$ is the change in log hazards for a one-unit change in $X_1$ when the rest of the covariates are held constant. The procedure assumes that this hypothesis will be tested using the Wald (or score) statistic

$$z = \frac{\hat{\beta}_1}{\sqrt{\text{Var}(\hat{\beta}_1)}}$$
**Power Calculations**

Suppose you want to test the null hypothesis that $\beta_i = 0$ versus the alternative that $\beta_i = \beta$. Hsieh and Lavori (2000) gave a formula relating sample size, $\alpha$, $\beta$, and $B$ when $X_i$ is normally distributed. The sample size formula is

$$D = \left(\frac{z_{1-\alpha/2} + z_{1-\beta}}{\sqrt{1 - R^2} \sigma^2 B^2}\right)^2$$

where $D$ is the number of events, $\sigma^2$ is the variance of $X_1$, and $R^2$ is the proportion of variance explained by the multiple regression of $X_1$ on the remaining covariates. It is interesting to note that the number of censored observations does not enter into the power calculations. To obtain a formula for the sample size, $N$, we inflate $D$ by dividing by $P$, the proportion of subjects that fail. Thus, the formula for $N$ is

$$N = \frac{\left(\frac{z_{1-\alpha/2} + z_{1-\beta}}{\sqrt{1 - R^2} \sigma^2 B^2}\right)^2}{P\left(1 - R^2\right) \sigma^2 B^2}$$

This formula is an extension of an earlier formula for the case of a single, binary covariate derived by Schoenfeld (1983). Thus, it may be used with discrete or continuous covariates.

**Assumptions**

It is important to note that this formulation assumes that proportional hazards model with $k$ covariates is valid. However, it does not assume exponential survival times.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. Under most situations, you will select either Beta for a power analysis or N for sample size determination.

Select N when you want to calculate the sample size needed to achieve a given power and alpha level.

Select Beta when you want to calculate the power of an experiment.

B (Log Hazard Ratio)

This procedure calculates power or sample size for testing the hypothesis that $\beta_i = 0$ versus the alternative that $\beta_i = B$ in a Cox regression. Enter one or more values of B here.

$B$ is the predicted change in log (base e) hazards corresponding to a one unit change in X1 when the other covariates are held constant. Thus, if you want to detect a hazard ratio of 1.5, enter $\ln(1.5) = 0.4055$. Although any non-zero value may be entered, common values are between -3 and 3.

S (Std Deviation of X1)

Enter an estimate of the standard deviation of X1, the predictor variable of interest. The formulation used here assumes that X1 follows the normal distribution. However, you can obtain approximate results for non-normal variables by putting in the correct value here. For example, if X1 is binary, the standard deviation is given by $\sqrt{p(1-p)}$ where $p$ is the proportion of either of the binary values in the population of X1.

If you don’t have an estimate, you can press the SD button to obtain a window that will help you determine a rough estimate of the standard deviation.

R-Squared Other X’s

This is the R-Squared that is obtained when X1 is regressed on the other X’s (covariates) in the model. Use this to account for the influence on power and sample size of adding other covariates. Note that the number of additional variables does not matter in this formulation. Only their overall relationship with X1 through this R-Squared value is used.

Of course, this value is restricted to being greater than or equal to zero and less than one. Use zero when there are no other covariates.
P (Overall Event Rate)
Enter one or more values for the event rate. The event rate is the proportion of subjects in which the event of interest occurs during the duration of the study. This is the proportion of non-censored subjects. Since the values entered here are proportions, they must be in the range $0 < P \leq 1$.

Note that when this value is set to 1.0, the sample size is the number of events (deaths).

Hypothesis Test
Specify whether the test is one-sided or two-sided. When a two-sided hypothesis is selected, the value of alpha is halved by PASS. Everything else remains the same.

Note that the accepted procedure is to use the Two Sided option unless you can justify using a one-sided test.

N (Sample Size)
This option specifies the total number of observations in the sample. You may enter a single value or a list of values.

Note that when the Overall Event Rate is set to 1.0, the sample size becomes the number of events.

Alpha (Significance Level)
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal probabilities when in fact they are equal.

Values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal probabilities of the event of interest when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was used for beta. Now, 0.10 is more popular. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.
Example1 - Power for Several Sample Sizes

Cox regression will be used to analyze the power of a survival time study. From past experience, the researchers want to evaluate the sample size needs for detecting regression coefficients of 0.2 and 0.3 for the independent variable of interest. The variable has a standard deviation of 1.20. The $R$-squared of this variable with seven other covariates is 0.18.

The event rate is thought to be 70% over the 3-year duration of the study. The researchers will test their hypothesis using a 5% significance level with a two-sided Wald test. They decide to calculate the power at sample sizes between 5 and 250.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions
- Power is the probability of rejecting a false null hypothesis. It should be close to one.
- N is the size of the sample drawn from the population.
- B is the size of the regression coefficient to be detected.
- SD is the standard deviation of X1.
- P is the event rate.
- R2 is the R-squared achieved when X1 is regressed on the other covariates.
- Alpha is the probability of rejecting a true null hypothesis.
- Beta is the probability of accepting a false null hypothesis.

Summary Statements
- A Cox regression of the log hazard ratio on a covariate with a standard deviation of 1.2000 based on a sample of 5 observations achieves 6% power at a 0.93983 significance level to detect a regression coefficient equal to 0.2000. The sample size was adjusted since a multiple regression of the variable of interest on the other covariates in the Cox regression is expected to have an R-Squared of 0.1800. The sample size was adjusted for an anticipated event rate of 0.7000.

This report shows the power for each of the scenarios.

Plot Section
Example2 - Validation Using Hsieh

Hsieh and Lavori (2000) present an example which we will use to validate this program. In this example, \( B = 1.0, S = 0.3126, R^2 = 0.1837, P = 0.738, \) one-sided alpha = 0.05, and power = 0.80. They calculated \( N = 107. \)

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

<table>
<thead>

</tbody>
</table>

Annotated Output

Click the Run button to perform the calculations and generate the following output.

Numeric Results

<table>
<thead>
<tr>
<th>Power</th>
<th>Sample Size (N)</th>
<th>Reg. Coef. (B)</th>
<th>S.D. of X1 (SD)</th>
<th>Event Rate (P)</th>
<th>R-Squared X1 vs Other X’s (R2)</th>
<th>One-Sided Alpha</th>
<th>Beta</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.80321</td>
<td>106</td>
<td>1.000</td>
<td>0.313</td>
<td>0.738</td>
<td>0.184</td>
<td>0.05000</td>
<td>0.19679</td>
</tr>
</tbody>
</table>

Note that \( PASS \) calculated 106 rather than the 107 calculated by Hsieh and Lavori (2000). The discrepancy is due to the intermediate rounding that they did. To show this, we will run a second example from Hsieh and Lavori in which \( R^2 = 0 \) and \( P = 1.0. \) In this case, \( N = 64. \)

Numeric Results with \( R^2 = 0 \) and \( P = 1.0 \)

<table>
<thead>
<tr>
<th>Power</th>
<th>Sample Size (N)</th>
<th>Reg. Coef. (B)</th>
<th>S.D. of X1 (SD)</th>
<th>Event Rate (P)</th>
<th>R-Squared X1 vs Other X’s (R2)</th>
<th>One-Sided Alpha</th>
<th>Beta</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.80399</td>
<td>64</td>

<td>0.313</td>
<td>1.000</td>
<td>0.000</td>
<td>0.05000</td>
<td>0.19601</td>
</tr>
</tbody>
</table>

Note that \( PASS \) also calculated 64. Hsieh and Lavori obtained the 107 by adjusting this 64 for \( P \) first and then for \( R^2. \) \( PASS \) does both adjustments at once, obtaining the 106. Thus, the difference is due to intermediate rounding.
Example3 - Validation for Binary X1 using Schoenfeld

Schoenfeld (1983), page 502, presents an example for the case when X1 is binary. In this example, \( B = \ln(1.5) = 0.4055 \), \( S = 0.5 \), \( R^2 = 0.0 \), \( P = 0.71 \), one-sided alpha = 0.05, and power = 0.80. Schoenfeld calculated \( N = 212 \).

Setup

You can enter these values yourself or load the Example3 template from the Template tab.

Chapter 855

Linear Regression

Introduction
Linear regression is a commonly used procedure in statistical analysis. One of the main objectives in linear regression analysis is to test hypotheses about the slope (sometimes called the regression coefficient) of the regression equation. This module calculates power and sample size for testing whether the slope is a value other than the value specified by the null hypothesis.

Difference between Linear Regression and Correlation
The correlation coefficient is used when both $X$ and $Y$ are from the normal distribution (in fact, the assumption actually is that $X$ and $Y$ follow a bivariate normal distribution). That is, $X$ is assumed to be a random variable whose distribution is normal. In the linear regression context, no statement is made about the distribution of $X$. In fact, $X$ is not even a random variable. Instead, it is a set of fixed values such as 10, 20, 30 or -1, 0, 1. Because of this difference in definition, we have included both Linear Regression and Correlation algorithms. They gave different results. This module deals with the Linear Regression (fixed $X$) case.

Technical Details
Suppose that the dependence of a variable $Y$ on another variable $X$ can be modeled using the simple linear equation

$$Y = A + BX$$

In this equation, $A$ is the $Y$-intercept, $B$ is the slope, $Y$ is the dependent variable, and $X$ is the independent variable.

The nature of the relationship between $Y$ and $X$ is studied using a sample of $N$ observations. Each observation consists of a data pair: the $X$ value and the $Y$ value. The values of $A$ and $B$ are estimated from these observations. Since the linear equation will not fit the observations exactly, estimated values of $A$ and $B$ must be used. These estimates are found using the method of least squares. Using these estimated values, each data pair may be modeled using the equation

$$Y_i = a + bX_i + e_i$$
Note that $a$ and $b$ are the estimates of the population parameters $A$ and $B$. The $e$ values represent the discrepancies between the estimated values $(a + bX)$ and the actual values $Y$. They are called the errors or residuals.

If it is assumed that these $e$ values are normally distributed, tests of hypotheses about $A$ and $B$ can be constructed. Specifically, we can employ an $F$ ratio to test the null hypothesis that the slope is $B0$ versus the alternative hypothesis that the slope is $B$ ($B$ not $B0$). The power function of this F test can be written

$$Power = Pr(F > F_a)$$

where $F_a$ is the critical value based on the central-$F$ distribution with 1 and $N - 2$ degrees of freedom and the significant level $\alpha$ and $F$ is distributed as a non-central $F$ with degrees of freedom 1 and $N - 2$ and non-centrality parameter $\lambda$. The value of $\lambda$ is

$$\lambda = N\left(\frac{SX(B - B0)}{\sigma}\right)^2$$

where $\sigma^2$ is the variance of the $e$’s and

$$SX = \sqrt{\frac{\sum_{i=1}^{N}(X_i - \bar{X})^2}{N}}$$

The values of each of the parameters $\alpha$, $\beta$, $\sigma^2$, $N$, $SX$, and $B$ can be determined from the others using the above formulation.

Note that the power for a one-sided test may be found by using $2\alpha$ for $\alpha$ in the above formulation.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters.

B0 (Slope|H0)

This is the value of the slope assumed by the null hypothesis. Often this value is set to zero, but this is not necessary. The alternative hypothesis is that the slope is not equal to this value.

B (Slope|H1)

This is the value of the slope at which the power is computed. The hypothesis being tested is that the slope is some value other than B0.

SX (Std Deviation of X’s)

This is the standard deviation of the X values in the sample. It is not necessarily the standard deviation of X in the population. For example, suppose the X values are five -1’s and five 1’s. The computed standard deviation of these values (dividing by N rather than N - 1) is 1.0.

You will often want to compute the power or sample size for a specific set of X values. Instead of computing SX by hand, you can use the keyword XS (short for X’s) followed by the list of X values. For example, the phrase

XS -1,1

is translated into a 1.0 (which is the standard deviation of these two values). This calculation assumes that the sample is allocated equally to the two values. Hence, an N of 10 implies that five are assigned to -1 and five to 1.

If you are planning a study involving two random variables, X and Y, that come from a bivariate normal population, you should enter the actual standard deviation of X here.

Residual Variance Method

The standard deviation of the residuals is needed for the power and sample size calculations. These residuals are the ei in the regression model

\[ Y_i = a + bX_i + e_i \]

However, their standard deviation is not available until after the study is complete. PASS provides three methods for specifying the standard deviation of the residuals: Std Deviation of Y, Correlation, and specifying it directly.
SY (Std Deviation of Y)
Enter an estimate of the standard deviation of $Y$. This standard deviation ignores $X$. An estimate of this value must be found from previous studies, pilot studies, or using your best guess. This option is used when 'Residual Variance Method' is set to 'SY'.

When this value is used, the standard deviation of the residuals is computed using the relationship

$$\sigma = \sqrt{\sigma_Y^2 - B^2SX^2}$$

This value must be greater than zero.

Correlation
Enter an estimate of the correlation between $Y$ and the $X$ values. An estimate of this correlation must be found from previous studies, pilot studies, or using your best guess. This value must be greater than zero and less than one—negative values are allowed. This option is used when 'Residual Variance Method' is set to 'R'.

When this method is used, the standard deviation of the residuals is computed using the relationship

$$\sigma = B(SX)\sqrt{1 / R^2 - 1}$$

where $R$ is the correlation.

S (Std Dev of Residuals)
Enter an estimate for the value of the standard deviation of the residuals. This option is used when 'Residual Variance Method' is set to 'S'.

N (Sample Size)
This is the number of observations in the study.

Alpha
This option specifies one or more values for the significance level--probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

The $F$ test corresponds to a two-sided test of the hypothesis that slopes are equal versus the alternative that they are unequal.

Values between 0.001 and 0.100 are acceptable. The value of 0.05 has become the standard. This means that about one test in twenty will falsely reject the null hypothesis. Although 0.05 is the standard value, you should pick a value for alpha that represents the risk of a type-I error you are willing to take.

Note that you can enter a range of values such as $0.01, 0.05$ or $0.01$ to $0.05$ by $0.01$. 
**Beta (1-Power)**

This option specifies one or more values for beta (the probability of accepting a false null hypothesis). Since statistical power is equal to one minus beta, specifying beta implicitly specifies the power. For example, setting beta at 0.20 also sets the power to 0.80.

Values must be between zero and one. The value of 0.20 has often used for beta. However, you should pick a value for beta that represents the risk of this type of error you are willing to take.

Note that you can enter a range of values such as 0.10, 0.20 or 0.05 to 0.20 by 0.05.

If your only interest is in determining the appropriate sample size for a confidence interval, set beta to 0.5.

**Options Tab**

This tab sets a couple of options used in the iterative procedures.

**Maximum Iterations**

Specify the maximum number of iterations allowed before the search for the criterion of interest is aborted. When the maximum number of iterations is reached without convergence, the criterion is left blank. A value of 500 is recommended.
**Example1 - Calculating the Power**

Suppose a power analysis must be conducted for a linear regression study that will test the relationship between two variables, \( Y \) and \( X \). The test will look at the power using two significance levels, 0.01 and 0.05 and several sample sizes between 5 and 85. Based on previous studies, the standard deviation of \( Y \) will be assumed to be 1.0. The standard deviation of the \( X \)'s in the sample will also be assumed as 1.0. The experimenter decides that unless the slope is at least 0.5, the relationship between \( X \) and \( Y \) is too weak to be considered.

**Setup**

You can enter these values yourself or load the Example1 template from the Template tab.

### Report Definitions

- **Power** is the probability of rejecting a false null hypothesis. It should be close to one.
- **N** is the size of the sample drawn from the population. To conserve resources, it should be small.
- **\( B_0 \)** is the slope under the null hypothesis.
- **\( B \)** is the slope at which the power is calculated.
- **SX** is the standard deviation of the X values.
- **SY** is the standard deviation of Y.
- **Alpha** is the probability of rejecting a true null hypothesis. It should be small.
- **Beta** is the probability of accepting a false null hypothesis. It should be small.

### Summary Statements

A sample size of 5 achieves 4% power to detect a change in slope from 0.00 under the null hypothesis to 0.50 under the alternative hypothesis when the standard deviation of the X's is 1.00, the standard deviation of Y is 1.00, and the two-sided significance level is 0.01000.

This report shows the calculated sample size for each of the scenarios.

### Plot Section

- **Power vs N by Alpha with Slope=0.50 SX=1.00 SY=1.00 F Test**

This plot shows the calculated sample size for each of the scenarios.
Example2 - Validation using Neter, Wasserman, and Kutner

Problem Statement
Neter, Wasserman, and Kutner (1983) pages 71 and 72 present a power analysis when \( N = 10 \), \( \text{Slope} = 0.25 \), \( \alpha = 0.05 \), \( SX = \sqrt{\frac{3400}{10}} = 18.439 \), and
\[
SY = \sqrt{10 + (0.25)^2 \left(\frac{3400}{10}\right)} = 5.59015.
\]
They found the power to be approximately 0.97.

Setup
You can enter these values yourself or load the Example2 template from the Template tab.

The power of 0.97975 matches their result to two decimals. Note that they used interpolation from a table to obtain their answer.
Logistic Regression

Introduction

Logistic regression expresses the relationship between a binary response variable and one or more independent variables called covariates. A covariate can be discrete or continuous.

Consider a study of death from disease at various ages. This can be put in a logistic regression format as follows. Let a binary response variable $Y$ be one if death has occurred and zero if not. Let $X$ be the individual’s age. Suppose a large group of various ages is followed for ten years and then both $Y$ and $X$ are recorded for each person. In order to study the pattern of death versus age, the age values are grouped into intervals and the proportions that have died in each age group are calculated. The results are displayed in the following plot.

As you would expect, as age increases, the proportion dying of disease increases. However, since the proportion dying is bounded below by zero and above by one, the relationship is approximated by an “S” shaped curve. Although a straight-line might be used to summarize the relationship between ages 40 and 60, it certainly could not be used for the young or the elderly.

Under the logistic model, the proportion dying, $P$, at a given age can be calculated using the formula

$$P = \frac{e^{\beta_0 + \beta_1 X}}{1 + e^{\beta_0 + \beta_1 X}}$$

This formula can be rearranged so that it is linear in $X$ as follows

$$\log\left( \frac{P}{1 - P} \right) = \beta_0 + \beta_1 X$$
Note that the left side is the logarithm of the odds of death versus non-death and the right side is a linear equation for $X$. This is sometimes called the logit transformation of $P$. When the scale of the vertical axis of the plot is modified using the logit transformation, the following straight-line plot results.

In the logistic regression model, the influence of $X$ on $Y$ is measured by the value of the slope of $X$ which we have called $\beta_1$. The hypothesis that $\beta_1 = 0$ versus the alternative that $\beta_1 = B \neq 0$ is of interest since if $\beta_1 = 0$, $X$ is not related to $Y$.

Under the alternative hypothesis that $\beta_1 = B$, the logistic model becomes

$$\log \left( \frac{P_1}{1 - P_1} \right) = \beta_0 + BX$$

Under the null hypothesis, this reduces to

$$\log \left( \frac{P_0}{1 - P_0} \right) = \beta_0$$

To test whether the slope is zero at a given value of $X$, the difference between these to quantities is formed giving

$$\beta_0 + BX - \beta_0 = \log \left( \frac{P_1}{1 - P_1} \right) - \log \left( \frac{P_0}{1 - P_0} \right)$$

which reduces to

$$BX = \log \left( \frac{P_1}{1 - P_1} \right) - \log \left( \frac{P_0}{1 - P_0} \right)$$

$$= \log \left( \frac{P_1 / (1 - P_1)}{P_0 / (1 - P_0)} \right)$$

$$= \log(OR)$$

where $OR$ is odds ratio of $P_1$ and $P_0$. This relationship may be solved for $OR$ giving

$$OR = e^{BX}$$
This shows that the odds ratio of $P_1$ and $P_0$ is directly related to the slope of the logistic regression equation. It also shows that the value of the odds ratio depends on the value of $X$. For a given value of $X$, testing that $B$ is zero is equivalent to testing OR is one. Since OR is commonly used and well understood, it is used as a measure of effect size in power analysis and sample size calculations.

**Power Calculations**

Suppose you want to test the null hypothesis that $\beta_1 = 0$ versus the alternative that $\beta_1 = B$.

Hsieh, Block, and Larsen (1998) have presented formulae relating sample size, $\alpha$, power, and $B$ for two situations: when $X_1$ is normally distributed and when $X_1$ is binomially distributed.

When $X_1$ is normally distributed, the sample size formula is

$$N = \frac{\left(z_{1-\alpha/2} + z_{1-\beta}\right)^2}{P^* (1 - P^*) B^2}$$

where $P^*$ is the event rate (probability that $Y = 1$) at the mean of $X_1$. Note that $B$ is defined in terms of an increase of one standard deviation of $X_1$ above the mean.

When $X_1$ is binomially distributed and $X_1 = 0$ or 1, the sample size formula is

$$N = \frac{\left(z_{1-\alpha/2} \sqrt{\frac{P(1 - P)}{R}} + z_{1-\beta} \sqrt{P_0(1 - P_0) + \frac{P_1(1 - P)(1 - R)}{R}}\right)^2}{(P_0 - P_1)^2 (1 - R)}$$

where $P_0$ is the event rate at $X_1 = 0$ and $P_1$ is the event rate at $X_1 = 1$, $R$ is the proportion of the sample with $X_1 = 1$, and $P$ is the overall event rate given by

$$P = (1 - R) P_0 + R P_1.$$
Multiple Logistic Regression

The multiple logistic regression model relates the probability distribution of \( Y \) to two or more covariates \( X_1, X_2, \cdots, X_k \) by the formula

\[
\log\left( \frac{P}{1-P} \right) = \beta_0 + \beta_1 X_1 + \cdots + \beta_k X_k
\]

where \( P \) is the probability that \( Y = 1 \) given the values of the covariates. It is a simple extension of the simple logistic regression model that was just presented. In power analysis and sample size work, attention is placed on a single covariate while the influence of the other covariates is statistically removed by placing them at their mean values.

When there are multiple covariates, the following adjustment was given by Hsieh (1998) to give the total sample size, \( N_m \)

\[
N_m = \frac{N}{1 - \rho^2}
\]

where \( \rho \) is the multiple correlation coefficient between \( X_1 \) (the variable of interest) and the remaining covariates. Notice that the number of extra covariates does not matter in this approximation.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are \( P1 \), \( N \), \( Alpha \), and \( Beta \). Under most situations, you will select either \( Beta \) for a power analysis or \( N \) for sample size determination.

Select \( N \) when you want to calculate the sample size needed to achieve a given power and alpha level.

Select \( Beta \) when you want to calculate the power of an experiment.

\( X \) (Independent Variable)

This option specifies whether the covariate is binary (binomial) or continuous (normal). This is a very important distinction since the sample size required for a particular power level is much larger for a binary covariate than for a continuous covariate.

This selection also changes the meaning of \( P0 \) and \( P1 \).

\( P0 \) (Baseline Prob \( Y=1 \))

This option specifies one or more \( P0 \) values. The interpretation of \( P0 \) depends on whether \( X_1 \) is binary or continuous.

Binomial Covariate

When \( X_1 \) is binary, \( P0 \) is the probability that \( Y = 1 \) when \( X_1 = 0 \). All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

\[
\log \left( \frac{P_0}{1 - P_0} \right) = \beta_0
\]

so that

\[
P_0 = \frac{e^{\beta_0}}{1 + e^{\beta_0}}
\]
**Normal Covariate**

When $X_1$ is normally distributed, $P_0$ is the probability that $Y = 1$ when $X_1 = \mu_{X_1}$, where $\mu_{X_1}$ is the mean of $X_1$. That is, $P_0$ is the baseline probability that $Y = 1$ when $X_1$ is ignored. All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

$$\log\left(\frac{P_0}{1-P_0}\right) = \beta_0 + \beta_{X_1}$$

so that

$$P_0 = \frac{e^{\beta_0 + \beta_{X_1} \mu_{X_1}}}{1 + e^{\beta_0 + \beta_{X_1} \mu_{X_1}}}$$

**Use P1 or Odds Ratio**

This option specifies the whether to specify $P1$ directly or to specify it by specifying the odds ratio. Since the relationship between the odds ratio, $P1$, and $P0$ is given by

$$OR = \frac{P_1 / (1-P_1)}{P_0 / (1-P_0)}$$

specifying $OR$ and $P0$ implicitly specifies $P1$.

This options lets you specify whether you want to state the alternative hypothesis in terms of $P1$ or the odds ratio.

**P1 (Alt. Prob Y =1)**

This option specifies the effect size to be detected by specifying $P1$. As was shown earlier, the slope of the logistic regression can be expressed in terms of $P_0$ and $P_1$. Hence, by specifying $P_1$, you are also specifying the slope.

This option is only used when the User P1 or Odds Ratio option is set to P1. Its interpretation depends on whether $X_1$ is binomial or normal.

**Binomial Covariate**

When $X_1$ is binary, $P1$ is the probability that $Y = 1$ when $X_1 = 1$. All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

$$\log\left(\frac{P_1}{1-P_1}\right) = \beta_0 + \beta_{X_1}$$

since $X_1 = 1$. 
Normal Covariate
When $X_i$ is normally distributed, $P1$ is the probability that $Y = 1$ when $X_i = \mu_{x_i} + \sigma_{x_i}$. That is, when $x_i$ is one standard deviation above the mean. All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

$$\log\left(\frac{P_i}{1 - P_i}\right) = \beta_0 + \beta_i x_i$$

so that

$$P_i = \frac{e^{\beta_0 + \beta_i x_i}}{1 + e^{\beta_0 + \beta_i x_i}}$$

Odds Ratio (Odds1/Odds0)
This option specifies the odds ratio to be detected by the study. As was shown earlier, the slope of the logistic regression can be expressed in terms of $P_0$ and the odds ratio. Hence, by specifying $OR$, you are also specifying the slope. Using the formula

$$P_i = \frac{OR(P_0)}{1 - P_0 + OR(P_0)}$$

specifying $OR$ and $P_0$ implicitly specifies $P_i$.

This option is only used when the User P1 or Odds Ratio option is set to Odds Ratio. Its interpretation depends on whether $X_i$ is binomial or normal.

Binomial Covariate
When $X_i$ is binary, this option gives the odds ratio of $P_i$ and $P_0$. All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

$$\log\left(\frac{P_i}{1 - P_i}\right) = \beta_0 + \beta_i$$

since $X_i = 0$.

This odds ratio compares the odds of obtaining $Y = 1$ when $X_i = 1$ to the odds of obtaining $Y = 1$ when $X_i = 0$. 
Normal Covariate
When $X_i$ is normally distributed, this option gives the odds ratio of $P_1$ and $P_0$, where $P_1$ is the probability that $Y = 1$ when $X_i = x_i$, where $x_i$ is a value other than $\mu_{x_i}$. All other covariates are assumed to be equal to their mean values. In this case, the logistic equation reduces to

$$\log\left(\frac{P_1}{1-P_1}\right) = \beta_0 + \beta_1 x_i$$

so that

$$P_1 = \frac{e^{\beta_0 + \beta_1 x_i}}{1 + e^{\beta_0 + \beta_1 x_i}}$$

This odds ratio compares the odds of obtaining $Y = 1$ when $X_i = x_i$ to the odds of obtaining $Y$ when $X_i = \mu_{x_i}$.

R-Squared Other X’s
This is the R-Squared that is obtained when $X_i$ is regressed on the other $X$’s (covariates) in the model. Use this to study the influence on power and sample size of adding other covariates. Note that the number of additional variables does not matter in this formulation. Only their overall relationship with $X_i$ through this R-Squared value is used.

Of course, this value is restricted to being greater than or equal to zero and less than one. Use zero when there are no other covariates.

Hypothesis Test
Specify whether the test is one-sided or two-sided. When a two-sided hypothesis is selected, the value of alpha is halved by PASS. Everything else remains the same.

Note that the accepted procedure is to use the Two Sided option unless you can justify using a one-sided test.

N (Sample Size)
This option specifies the total number of observations in the sample. You may enter a single value or a list of values.

% N with X = 1 (Binary Only)
When $X_i$ is binary, this option specifies the proportion, $R$, of the sample in which $X_i = 1$. Note that the value is specified as a percentage.
Alpha (Significance Level)
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal probabilities when in fact they are equal.

Values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal probabilities of the event of interest when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was used for beta. Now, 0.10 is becoming more popular. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80, respectively.
Example1 - Power for a Continuous Covariate

A study is to be undertaken to study the relationship between post-traumatic stress disorder and heart rate after viewing video tapes containing violent sequences. Heart rate is assumed to be normally distributed. The event rate is thought to be 7% among soldiers. The researchers want a sample size large enough to detect an odds ratios of 1.5 or 2.0 with 90% power at the 0.05 significance level with a two-sided test. They decide to calculate the power at level sample sizes between 20 and 1200.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

### Report Definitions

- **Power** is the probability of rejecting a false null hypothesis. It should be close to one.
- **N** is the size of the sample drawn from the population.
- **P₀** is the response probability at the mean of the covariate, X.
- **P₁** is the response probability when X is increased to one standard deviation above the mean.
- **Odds Ratio** is the odds ratio when P₁ is on top. That is, it is \([P₁/(1-P₁)]/[P₀/(1-P₀)]\).
- **R-Squared** is the R² achieved when X is regressed on the other independent variables in the regression.
- **Alpha** is the probability of rejecting a true null hypothesis.
- **Beta** is the probability of accepting a false null hypothesis.

### Summary Statements

A logistic regression of a binary response variable (Y) on a continuous, normally distributed, independent variable (X) with a sample size of 20 observations achieves 7% power at a 0.050 significance level to detect a change in Prob(Y=1) from the value of 0.070 at the mean of X to 0.101 when X is increased to one standard deviation above the mean. This change corresponds to an odds ratio of 1.500.

This plot shows the power versus the sample size for the two values of the odds ratio.
Example2 - Sample Size for a Continuous Covariate

Continuing with the previous study, determine the exact sample size necessary to attain a power of 90%.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

**PASS** calculates a power of 0.95021 which matches Hsieh.
Chapter 865

Multiple Regression

Introduction

The Linear Regression chapter dealt with the regression of a dependent variable on a single independent variable. This module deals with the general case of multiple regression in which there are two or more independent variables.

Instead of using the correlation coefficient as the index of interest, the square of the correlation coefficient, $R^2$, has been adopted, mainly because of its ease of interpretation and its ability to be partitioned among various subgroups of the independent variables. $R^2$ ranges from zero to one.

When performing a regression analysis, a typical hypothesis involves testing the significance of a subgroup of the independent variables after considering a second, nonoverlapping, group of independent variables. For example, suppose you have five independent variables. One common hypothesis tests whether a certain variable is influential (has a nonzero coefficient in the regression equation) after considering the other four variables. To perform this test, you partition the $R^2$ from fitting all five variables into the $R^2$ of the first four variables and the $R^2$ added by the fifth variable. An $F$-test is constructed that tests whether this second $R^2$ value is significantly different from zero. If it is, the fifth variable is significant after adjusting for the other four variables.
Definition of Terms

Cohen (1988) provides a comprehensive discussion of this topic. We strongly suggest that you refer to the examples given there for a thorough understanding of this subject. We will provide a brief introduction, concentrating on defining the terms and statistics that are used.

Consider a sample of $N$ rows of data. Suppose each row consists of the value of a dependent variable, $Y$, followed by the values of $k$ independent variables, $X_1, X_2, \ldots, X_k$. The multiple regression equation of $Y$ on the $X$’s is

$$Y_j = \beta_0 + \beta_1 X_{1j} + \beta_2 X_{2j} + \cdots + \beta_k X_{kj} + \varepsilon_j$$

The $\beta$’s are called the population regression coefficients or beta weights. They represent the true values in the population from which the sample was taken. Their sample estimates, $b_0, b_1, b_2, \ldots, b_k$, are calculated from the data using least squares methodology. The estimated regression equation becomes

$$Y_j = b_0 + b_1 X_{1j} + b_2 X_{2j} + \cdots + b_k X_{kj} + e_j$$

Upon removing the residuals, $e_j$, the predicted values are calculated as

$$\hat{Y}_j = b_0 + b_1 X_{1j} + b_2 X_{2j} + \cdots + b_k X_{kj}$$

$R^2$ is defined as the proportion of the variation of $Y$ that is explained (accounted for) by the variation in the $X$’s. The equation for $R^2$ is

$$R^2 = \frac{\sum_{i=1}^{N} (\hat{Y}_i - \bar{Y})^2}{\sum_{i=1}^{N} (Y_i - \bar{Y})^2}$$

or

$$R^2 = 1 - \frac{\sum_{i=1}^{N} e_i^2}{\sum_{i=1}^{N} (Y_i - \bar{Y})^2}$$

Notice that the numerator sum of squares in the above equations depend on the $X$’s through $\hat{Y}_j$. Therefore, each time you change the $X$’s included in the regression equation, you will obtain a different value of $R^2$. Hence, you need special notation to indicate on which $X$’s the particular $R^2$ is based.

Let $C$ and $T$ refer to subgroups of the $X$’s. Define $R_{TC}^2 = R_{TC}^2 - R_C^2$ to be the $R^2$ added when $Y$ is regressed on the variables in set $T$ after the variables in set $C$. Define $R_C^2$ to be the $R^2$ achieved when $Y$ is regressed on those in set $C$ ignoring the variables in set $T$. Define $R_{TC}^2$ to be the $R^2$ achieved when $Y$ is regressed on the variables in both sets $C$ and $T$. 
Using the above notation, you can construct $F$-tests that will test whether the $\beta$'s corresponding to certain sets of $X$'s are simultaneously zero while controlling for other variables. For example, to test the significance of the $X$'s in set $T$ while removing the influence of the $X$'s in set $C$ from experimental error, you would use:

$$F_{u,v} = \frac{(R_{T|C}^2)}{\left(1 - R_C^2 - R_{T|C}^2\right)/v}$$

where $u$ is the number of variables in $T$, $v = N-k-1$, and $k$ is the total number of variables in $C$ and $T$. Note that this formula includes the effect size, $f^2$.

$$f^2 = \frac{R_{T|C}^2}{1 - R_C^2 - R_{T|C}^2}$$

Most significance tests in regression analysis, correlation analysis, analysis of variance, and analysis of covariance may be constructed using these $F$-ratios.

For example, suppose the seven $X$'s available are dividing into two sets: set $C$ includes variables $X_1, X_3, X_6$ and set $T$ includes $X_2, X_4, X_5, X_7$. The above $F$-ratio tests the null hypothesis that $\beta_2 = \beta_4 = \beta_5 = \beta_7 = 0$ after adjusting for $X_1, X_3, X_6$.

### Calculating the Power

The calculation of the power of a particular test proceeds as follows:

1. Determine the critical value, $F_{u,v,\alpha}$ where $u$ is the numerator degrees of freedom, $v$ is the denominator degrees of freedom, and $\alpha$ is the probability of a type-I error.

2. Calculate the noncentrality parameter $\lambda$ using the formula:

$$\lambda = N \frac{R_{T|C}^2}{1 - R_C^2 - R_{T|C}^2}$$

3. Compute the power as the probability of being greater than $F_{u,v,\alpha}$ on a noncentral-$F$ distribution with noncentrality parameter $\lambda$.

Note that the formula for $\lambda$ is different from that used in PASS 6.0. The algorithm used in PASS 6.0 was based on formula (9.3.1) in Cohen (1988) which gives approximate answers. This version of PASS using an algorithm that gives exact answers.
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. The parameters that may be selected are $R^2$, $N$, $Alpha$, and $Beta$. Under most situations, you will select either $Beta$ or $N$.

Select $N$ when you want to calculate the sample size needed to achieve a given power and alpha level.

Select $Beta$ when you want to calculate the power of an experiment.

T: Variables Tested

These options refer to the set of independent variables ($X's$) whose coefficients are to be tested to determine if they all are zero. That is, this is the set of variables to be tested for statistical significance.

Number

This option specifies the number of variables in $T$. This is $u$. This number must be greater than or equal to one. Note that the total number of variables specified in the two Number options must be less than $N - 1$.

R2 Added

This box specifies the increase in $R^2$ due to the variables in set $T$ after including the variables in set $C$ in the regression equation. Note that this amount must be between zero and one and that the total of the two $R^2$ values must be less than one.
C: Variables Controlled
These options refer to the independent variables (\(X\)’s) to be controlled (adjusted) for (these are the variables in set \(C\)). That is, the influence of these variables is statistically removed. These are variables that are included in the regression equation but are not being tested for statistical significance.

Number
This option specifies the number of variables in \(C\). This number must be greater than or equal to zero. Note that the total number of variables specified in the two Number options must be less than \(N-1\).

R2 Added
This box specifies the \(R^2\) achieved by the variables in set \(C\) when they are fit alone in the regression equation. Note that this amount must be between zero and one and that the total of the two \(R^2\) values must be less than one.

N (Sample Size)
This option specifies the value(s) for \(N\), the sample size. Note that this value must be at least one greater than the total number of variables specified in sets \(C\) and \(T\).

Alpha (Significance Level)
This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis when in fact it is true.

Values must be between zero and one. Historically, the value of 0.05 was used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.

Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal correlations when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was often used for beta. However, you should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.
Example 1 - Testing the addition or deletion of a single variable

This example calculates the power of an $F$ test constructed to test a fifth variable which adds 0.05 to $R^2$ after considering four other variables whose combined $R^2$ value is 0.50. Sample sizes from 10 to 150 will be investigated. The significance level is 0.05.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example1 by clicking the Template tab and loading this template.

Report Definitions

Power is the probability of rejecting a false null hypothesis. 
N is the number of observations on which the multiple regression is computed. 
Alpha is the probability of rejecting a true null hypothesis. It should be small. 
Beta is the probability of accepting a false null hypothesis. It should be small. 
Cnt refers to the number of independent variables in that category. 
R² is the amount that is added to the overall R-Squared value by these variables. 
Ind. Variables Tested are those variables whose regression coefficients are tested against zero. 
Ind. Variables Controlled are those variables whose influence is removed from experimental error.

Summary Statements

A sample size of 10 achieves 13% power to detect an R-Squared of 0.05000 attributed to 1 
independent variable(s) using an F-Test with a significance level (alpha) of 0.05000. The 
variables tested are adjusted for an additional 4 independent variable(s) with an R-Squared of 
0.50000.

This report shows the values of each of the parameters, one scenario per row. The definitions of 
each of the columns is given in the Report Definitions section. 
Note that in this particular example, a reasonable power of 0.90 is not reached until the sample 
size is 110.

Plots Section

This plot shows the relationship between sample size and power.
Example 2 - Minimum Detectable $R^2$ Squared

Suppose the researcher in Example 1 can only afford a sample size of 30. He wants to know the minimum detectable $R^2$ that can be detected if the power is 80% and 90%.

Setup

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load and run the Example2 template.

</tr>
</tbody>
</table>

This report shows that at 90% power, a sample size of 30 cannot detect an $R^2$ less than 0.13787.
Example 3 - Sample Size, Many X’s

Suppose you have 25 observations on 19 independent variables. You run a regression analysis with all 19 variables and obtain an $R^2$ value of 0.90. You find that 4 of these variables will result in an $R^2$ of 0.60, leaving an $R^2$ increment of 0.30 for the other 15. You decide to test the significance of these 15 variables. The $F$ ratio is

$$F_{15,5} = \frac{(0.90 - 0.60)/15}{(1.0 - 0.90)/5} = 1.0$$

Obviously, an $F$ of 1.0 is nonsignificant, so you might be tempted to discard these variables and proceed with the four that are significant. Before doing so, you decided to do a power analysis on this $F$ test.

**Setup**

This section presents the values of each of the parameters needed to run this example. You can make these changes directly on your screen or you can load the template entitled Example3 by clicking the Template tab and loading this template.

The power of 0.96829 matches O’Brien’s result.
Chapter 870

Poisson Regression

Poisson regression is used when the dependent variable is a count. Following the results of Signorini (1991), this procedure calculates power and sample size for testing the hypothesis that $\beta_1 = 0$ versus the alternative that $\beta_1 = B$. Note that $e^{\beta_1}$ is the change in the rate for a one-unit change in $X_1$ when the rest of the covariates are held constant. The procedure assumes that this hypothesis will be tested using the score statistic

$$z = \frac{\hat{\beta}_1}{\sqrt{\text{Var}(\hat{\beta}_1)}}$$

The Poisson Distribution

The Poisson distribution models the probability of $y$ events (i.e. failure, death, or existence) with the formula

$$\Pr(Y = y|\mu) = \frac{e^{-\mu} \mu^y}{y!} \quad (y = 0,1,2,...)$$

Notice that the Poisson distribution is specified with a single parameter $\mu$. This is the mean incidence rate of a rare event per unit of exposure. Exposure may be time, space, distance, area, volume, or population size. Because exposure is often a period of time, we use the symbol $t$ to represent the exposure. When no exposure value is given, it is assumed to be one. 

The parameter $\mu$ may be interpreted as the risk of a new occurrence of the event during a specified exposure period, $t$. The probability of $y$ events is then given by

$$\Pr(Y = y|\mu, t) = \frac{e^{-\mu t} (\mu t)^y}{y!} \quad (y = 0,1,2,...)$$

The Poisson distribution has the property that its mean and variance are equal.
The Poisson Regression Model

In Poisson regression, we suppose that the Poisson incidence rate $\mu$ is determined by a set of $k$ regressor variables (the $X$’s). The expression relating these quantities is

$$
\mu = \exp(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_k X_k)
$$

The regression coefficients $\beta_0, \beta_1, \beta_2, \cdots, \beta_k$ are unknown parameters that are estimated from a set of data. Their estimates are labeled $b_0, b_1, \cdots, b_k$.

Using this notation, the fundamental Poisson regression model for an observation $i$ is written as

$$
\Pr(Y_i = y_i|\mu_i, t_i) = \frac{e^{-\mu_i}(\mu_i^{y_i})}{y_i!}
$$

where

$$
\mu_i = \lambda(x_i|\beta) = \exp(\beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \cdots + \beta_k X_{ki})
$$

That is, for a given set of values of the regressor variables, the outcome follows the Poisson distribution.
Power Calculations

Suppose you want to test the null hypothesis that $\beta_1 = 0$ versus the alternative that $\beta_1 = B1$. Signorini (1991) gives the formula relating sample size, $\alpha$, $\beta$, and $B1$ when $X_1$ is the only covariate of interest as

$$N = \phi \left( z_{1-\alpha/2} \sqrt{V(b_1|\beta_1 = 0) + z_{1-\beta} \sqrt{V(b_1|\beta_1 = B1)}} \right)^2$$

where $N$ is the sample size, $\phi$ is a measure of over-dispersion, $\mu_T$ is the mean exposure time, and $z$ is the standard normal deviate. Following the extension used in Hsieh, Block, and Larsen (1998) and Hsieh and Lavori (2000), when there are other covariates, PASS uses the approximation

$$N = \phi \left( z_{1-\alpha/2} \sqrt{V(b_1|\beta_1 = 0) + z_{1-\beta} \sqrt{V(b_1|\beta_1 = B1)}} \right)^2$$

where $R^2$ is the square of the multiple correlation coefficient when the covariate of interest is regressed on the other covariates. The variance in the null case is given by

$$V(b_1|\beta_1 = 0) = \frac{1}{\text{Var}(X_1)}$$

The variance for the non-null case depends on the underlying distribution of $X$. Common choices are given next.

Normal

$$V(b_1|\beta_1 = B1) = e^{\left( \frac{B1 \mu_{X1} + B1^2 \sigma_{X1}^2}{2} \right)}$$

$$V(X_1) = \sigma_{X1}^2$$

Exponential

$$V(b_1|\beta_1 = B1) = \frac{(\lambda_{X1} - B)^3}{\lambda_{X1}}$$

$$V(X_1) = \lambda_{X1}^2$$
Uniform, on the interval \([C, D]\)

\[
V(b_i|\beta_i = B1) = \frac{m}{m(m_{11}) - m_i^2}
\]

\[
V(X1) = \frac{(D - C)^2}{12}
\]

where

\[
m = \frac{e^{B1D} - e^{B1C}}{(D - C)B1}
\]

\[
m_i = \frac{e^{B1D}(B1D - 1) - e^{B1C}(B1C - 1)}{(D - C)B1^2}
\]

\[
m_{11} = \frac{e^{B1D}(2 - 2B1D + B1^2D^2) - e^{B1C}(2 - 2B1C + B1^2C^2)}{(D - C)B1^3}
\]

Binomial, Parameter \(\pi_{X1}\)

\[
V(b_i|\beta_i = B1) = \frac{1}{1 - \pi_{X1}} + \frac{1}{\pi_{X1}e^{B1}}
\]

\[
V(X1) = \pi_{X1}(1 - \pi_{X1})
\]
Procedure Options

This section describes the options that are unique to this procedure. These are located on the panels associated with the Data, Options, and Reports tabs. To find out more about using the other tabs such as Plot Text, Axes, and Template, turn to the chapter entitled Procedure Templates.

Data Tab

The Data tab contains most of the parameters and options that you will be concerned with.

Find

This option specifies the parameter to be solved for from the other parameters. Under most situations, you will select either Beta for a power analysis or N for sample size determination.

Select N when you want to calculate the sample size needed to achieve a given power and alpha level. Select Beta when you want to calculate the power of an experiment.

Exp(B1)/Exp(B0) (Rate Ratio)

B1 is the value of the regression coefficient under the alternative hypothesis. In Poisson regression, it is more natural to specify a value for exp(B1)/exp(B0) than for B1 because exp(B1)/exp(B0) represents the ratio of the response rate when X1 is increased one unit and all other covariates are constant to its baseline rate. Depending on the dataset being analyzed, the response rate might be the hazard rate, death rate, survival rate, or accident rate.

For example, suppose the baseline response rate (the value of \( \exp(\beta_0) \)) is 0.70 and you want the study to be large enough to detect a 30% increase in the response rate. The value entered here would be 1.3.

Alpha (Significance Level)

This option specifies one or more values for the probability of a type-I error (alpha). A type-I error occurs when you reject the null hypothesis of equal probabilities when in fact they are equal.

Values must be between zero and one. Historically, the value of 0.05 has been used for alpha. This means that about one test in twenty will falsely reject the null hypothesis. You should pick a value for alpha that represents the risk of a type-I error you are willing to take in your experimental situation.
Beta (1 - Power)
This option specifies one or more values for the probability of a type-II error (beta). A type-II error occurs when you fail to reject the null hypothesis of equal probabilities of the event of interest when in fact they are different.

Values must be between zero and one. Historically, the value of 0.20 was used for beta. Now, 0.10 is more popular. You should pick a value for beta that represents the risk of a type-II error you are willing to take.

Power is defined as one minus beta. Power is equal to the probability of rejecting a false null hypothesis. Hence, specifying the beta error level also specifies the power level. For example, if you specify beta values of 0.05, 0.10, and 0.20, you are specifying the corresponding power values of 0.95, 0.90, and 0.80.

R-Squared Other X’s
This is the $R^2$ that is obtained when $X_1$ is regressed on the other $X$’s (covariates) in the model. Use this to account for the influence on power and sample size of adding other covariates. Note that the number of additional variables does not matter in this formulation. Only their overall relationship with $X_1$ through this R-Squared value is used.

Of course, this value is restricted to being greater than or equal to zero and less than one. Use zero when there are no other covariates.

Phi (Over-Dispersion Parameter)
Phi is the over-dispersion parameter for Poisson regression. When there is no over-dispersion, set this value to one.

Exp(B0) (Baseline Rate)
Exp(B0) is the baseline response rate. This is the response rate that occurs when all covariates are equal to zero. Depending on the dataset being analyzed, the response rate might be the hazard rate, death rate, survival rate, or accident rate.

Mu T (E Time)
This is the mean exposure time, $\mu_T$, over which the response rate is calculated. If the response rates are for one year, enter 1 here. If they are for 30 days, enter 30 here.

Hypothesis Test
Specify whether the test is one-sided or two-sided. When a two-sided hypothesis is selected, the value of alpha is halved by $PASS$. Everything else remains the same.

Note that the accepted procedure is to use the Two-Sided option unless you can justify using a one-sided test.
N (Sample Size)
This option specifies the total number of observations in the sample. You may enter a single value or a list of values.

Note that when the Overall Event Rate is set to 1.0, the sample size becomes the number of events.

X Distribution
This option specifies the distribution of the covariate being analyzed. You can choose from the normal, exponential, uniform, and binomial distributions. Once you have selected the anticipated distribution of the covariate, you must also specify the distribution’s parameter(s).

Normal(M)
This option is used when the X Distribution is set to Normal(M,S) to specify the mean of the covariate distribution.

Normal(S)
This option is used when the X Distribution is set to Normal(M,S) to specify the standard deviation of the covariate distribution.

Uniform(C)
This option is used when the X Distribution is set to Uniform(C,D) to specify the minimum of the covariate distribution. That is, the distribution of the covariate is assumed to range from C to D.

Uniform(D)
This option is used when the X Distribution is set to Uniform(C,D) to specify the maximum of the covariate distribution. That is, the distribution of the covariate is assumed to range from C to D.

Binomial(P)
This option is used when the X Distribution is set to Binomial(P) to specify the proportion associated with the covariate. For example, if the covariate being studied is an indicator variable of treatment and control and you anticipated having an equal number of treatments and controls, this value should be set to 0.50.

Exponential(L)
This option is used when the X Distribution is set to Exponential(L) to specify the lambda associated with the covariate. Note that the pdf of the exponential distribution is assumed to be \((\lambda) \exp(-\lambda X)\).
Example 1 - Power for Several Sample Sizes

Poisson regression will be used to analyze the power for a study of the relationship between the number of flaws on a manufactured article and the experience (measured in years) of the operator. The researchers want to evaluate the sample size needs for detecting ratios in response rates of 1.3 and 1.5. The experience of an operator is assumed to be normally distributed with mean 3.2 and standard deviation 2.1. No other covariates will be included in the analysis. The researchers will test their hypothesis using a 5% significance level with a two-sided Wald test. They decide to calculate the power at sample sizes between 5 and 50.

Setup

You can enter these values yourself or load the Example1 template from the Template tab.

Report Definitions

Power is the probability of rejecting a false null hypothesis. It should be close to one.
N is the size of the sample drawn from the population.
Exp(B1)/Exp(B0) is the response rate ratio due to a one-unit change in X1.
Exp(B0) is the response rate when all covariates have a value of zero.
Phi is the over-dispersion parameter used when the Poisson model does not fit.
R2 is the R-squared achieved when X1 is regressed on the other covariates.
Alpha is the probability of rejecting Exp(B1)/Exp(B0) is one.
Beta is the probability of accepting a false null hypothesis.

Summary Statements

A Poisson regression of a dependent variable of counts on normally distributed independent variable with mean = 3.2 and standard deviation = 2.1 using a sample of 5 observations achieves 28% power at a 0.71534 significance level to detect a response rate ratio of at least 1.3000 due to a one-unit change in the IV. The baseline rate is 1.0000 and the mean exposure time is 1.0000.

This report shows the power for each of the scenarios. Note that if you were interested in $B_1$ instead of $\exp(B_1)$, you would simply take the natural logarithm of the value of $\exp(B_1)$.

Plot Section
Example2 - Validation Using Signorini

Signorini (1991), page 449, presents an example which we will use to validate this program. In the example, \( \text{Exp}(B_1)/\text{Exp}(B_0) = 1.3, \text{Exp}(B_0) = 0.85, R^2 = 0.0, \text{Mu} \ T = 1.0, \) and \( \Phi = 1.0. \) The independent variable is assumed to be binomial with proportion 0.5. A one-sided test with alpha = 0.05 will be used. Sample sizes for power = 0.80, 0.90, and 0.95 are calculated to be 406, 555, and 697.

Setup

You can enter these values yourself or load the Example2 template from the Template tab.

### Option Value

</table>

Note that **PASS** calculated 556 rather than the 555 calculated by Signorini (1991). The discrepancy is due to rounding.
Chapter 900

Chi-Square Effect Size Estimator

Introduction
This procedure calculates the effect size of the Chi-square test for use in power and sample size calculations. Based on your input, the procedure provides effect size estimates for Chi-square goodness-of-fit tests and for Chi-square tests of independence.

The Chi-square test is often used to test whether sets of frequencies or proportions follow certain patterns. The two most common cases are in tests of goodness of fit and tests of independence in contingency tables.

The Chi-square goodness-of-fit test is used to test whether a set of data follows a particular distribution. For example, you might want to test whether a set of data comes from the normal distribution.

The Chi-square test for independence in a contingency table is another common application of this test. Here individuals (people, animals, or things) are classified by two (nominal or ordinal) classification variables into a two-way contingency table. This table contains the counts of the number of individuals in each combination of the row categories and column categories. The Chi-square test determines if there is dependence (association) between the two classification variables.
Effect Size

For each cell of a table containing \( m \) cells, there are two proportions considered: one specified by a null hypothesis and the other specified by the alternative hypothesis. Usually, the proportions specified by the alternative hypothesis are those occurring in the data. Define \( p_{0i} \) to be the proportion in cell \( i \) given by the null hypothesis and \( p_{1i} \) to be the proportion in cell \( i \) according to the alternative hypothesis. The effect size, \( W \), is calculated using the following formula:

\[
W = \sqrt{\frac{\sum_{i=1}^{m} (p_{0i} - p_{1i})^2}{p_{0i}}}.
\]

The formula for computing the Chi-square value, \( \chi^2 \), is

\[
\chi^2 = \sum_{i=1}^{m} \frac{(O_i - E_i)^2}{E_i}
\]

\[
= N \sum_{i=1}^{m} \frac{(p_{0i} - p_{1i})^2}{p_{0i}},
\]

where \( N \) is the total count in all the cells. Hence, the relationship between \( W \) and \( \chi^2 \) is

\[
\chi^2 = NW^2
\]

or

\[
W = \sqrt{\frac{\chi^2}{N}}
\]
Contingency Table Tab

This window allows you to enter up to an eight-by-eight contingency table. You can enter percentages or counts. If you enter counts, the Chi-Square and Prob Level values are correct and may be used to test the independence of the row and column variables. If you enter percentages, you should ignore the Chi-Square and Prob Level values.

Note that if you are entering percentages, it does not matter whether you enter table percentages or row (or column) percentages as long as you are consistent.

Example

Suppose you are planning a survey with the primary purpose of testing whether marital status is related to gender. You decide to adopt four marital status categories: never married, married, divorced, widowed. In the population you are studying, previous studies have found the following percentages in each of these categories:

- Never Married 27%
- Married 39%
- Divorced 23%
- Widowed 11%

You decide that you want to calculate the effect size when the individual percentages for males and females are

<table>
<thead>
<tr>
<th>Gender</th>
<th>Male</th>
<th>Female</th>
</tr>
</thead>
<tbody>
<tr>
<td>Never Married</td>
<td>22%</td>
<td>32%</td>
</tr>
<tr>
<td>Married</td>
<td>46%</td>
<td>33%</td>
</tr>
<tr>
<td>Divorced</td>
<td>22%</td>
<td>24%</td>
</tr>
<tr>
<td>Widowed</td>
<td>10%</td>
<td>11%</td>
</tr>
</tbody>
</table>

To complete this example, you would load the Chi-Square Effect Size Estimator procedure from the PASS-Other menu and enter “22 46 22 10” across the top row and “32 33 24 11” across the next row. The value of $W$ turns out to be 0.143626.

Note that even though a Chi-square value (4.13) and probability level (0.248) are displayed, you would ignore them since you have entered percentages, not counts, into the table. If you had entered counts, these results could be used to test the hypothesis of independence.
**Multinomial Table Tab**

This window allows you to enter a multinomial table with up to fourteen cells. You can enter percentages or counts. If you enter counts, the Chi-Square and Prob Level values are correct and may be used to test the statistical significance of the table. If you enter percentages, you should ignore the Chi-Square and Prob Level values.

Note that if you are using the window to perform a goodness-of-fit test on a set of data, you will need to adjust the degrees of freedom for the number of parameters you are estimating. For example, if you are testing whether the data are distributed normally and you estimate the mean and standard deviation from the data, you will need to reduce the degrees of freedom by two.

**Example**

Suppose you are going to use the Chi-square goodness-of-fit statistic calculated from a multinomial table to test whether a set of exponential data follow the normal distribution. That is, you want to find a reasonable effect size for comparing exponentially distributed data to the normal distribution.

You decide to divide the data into five groups: 5 or less, 5-10, 10-15, 15-20, 20+

Using tables for the normal and exponential distributions, you find that the probabilities for each group are

<table>
<thead>
<tr>
<th>Category</th>
<th>Normal</th>
<th>Exponential</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 or Less</td>
<td>11%</td>
<td>39%</td>
</tr>
<tr>
<td>5 to 10</td>
<td>20%</td>
<td>26%</td>
</tr>
<tr>
<td>10 to 15</td>
<td>38%</td>
<td>18%</td>
</tr>
<tr>
<td>15 to 20</td>
<td>20%</td>
<td>11%</td>
</tr>
<tr>
<td>Above 20</td>
<td>11%</td>
<td>6%</td>
</tr>
</tbody>
</table>

To complete this example, you would set the Chi-Square Effect Size Estimator procedure to the Multinomial Test tab and enter “11 20 38 20 11” down the first column and “39 26 18 11 6” down the second column. The calculated value of $W$ is 0.948271. You would enter this value into the Effect Size option of the Chi-Square Test window in **PASS** to determine the necessary sample size.
Chapter 905

Standard Deviation Estimator

Introduction

Even though it is not of primary interest, an estimate of the standard deviation ($SD$) is needed when calculating the power or sample size of an experiment involving one or more means. Finding such an estimate is difficult not only because the estimate is required before the data are available, but also because the interpretation of the standard deviation is vague and our experience with it is low. How do you estimate a quantity without data and without a clear understanding of what the quantity is? This section will acquaint you with the standard deviation and offer several ways to obtain a rough estimate of it before the experiment begins using the Standard Deviation Estimator.

The Standard Deviation Estimator can also be used to calculate the standard deviation of the means, a quantity used in estimating sample sizes in analysis of variance designs.

Understanding the Standard Deviation

How well do you understand the standard deviation from the formula below? How would you describe it to another person? That’s a tough task. Everyone understands an average, but what about a standard deviation?

In the paragraphs that follow, we will explain that the standard deviation has two general interpretations. **First, it may be thought of as the average difference between an observation and the mean, ignoring the sign. Second, that it may be thought of as the average difference between any two data values, ignoring the sign.**
The population standard deviation is calculated using the formula:

\[
\sigma = \sqrt{\frac{\sum_{i=1}^{N} (X_i - \mu)^2}{N}}
\]

where \( N \) is the number of items in the population, \( X \) is the variable being measured, and \( \mu \) is the mean of \( X \). This formula indicates that the standard deviation is the square root of an average. An average of what? An average of the squared differences between each value and the mean. The differences are squared to remove the sign so that negative values will not cancel out positive values. After summing up these squared differences and dividing by \( N \), the square root is taken to put the result back in the original scale. Bottom line—the standard deviation can be thought of as the average difference between the data values and their mean. (We are using the terms mean and average here. Both refer to the same operation.)

**An Example**

Consider the following two sets of numbers

A: 1, 5, 9
B: 4, 5, 6

Both sets have the same mean of 5. However, their standard deviations are quite different. Subtracting the mean and squaring the three items in each set results in

Set A

\[(1-5)(1-4) = 16\]
\[(5-5)(5-5) = 0\]
\[(9-5)(9-5) = 16\]

Sum = 32
\[SD = \sqrt{32/3} = 3.266\]

Set B

\[(4-5)(4-5) = 1\]
\[(5-5)(5-5) = 0\]
\[(6-5)(6-5) = 1\]

Sum = 2
\[SD = \sqrt{2/3} = 0.8165\]

The standard deviations show that the data in set A vary more than the data in set B.
Divide by N or N-1?

Note that we are dividing by \( N \), not \( N-1 \) as you usually see. When the standard deviation is computed using all values in the population, \( N \) is used as the divisor. However, when the standard deviation is calculate from a sample, \( N-1 \) is used as the divisor. In fact, we stress that the results are for a sample by using the lower-case \( n \) and naming the sample standard deviation \( S \). The value of \( S \) is computed from a sample of \( n \) values using the formula

\[
S = \sqrt{\frac{\sum_{i=1}^{n} (X_i - \overline{X})^2}{n-1}}
\]

The \( n-1 \) is used instead of the \( n \) to correct for bias that statisticians have discovered. That is, over the long run, dividing by \( n-1 \) provides a better estimate of \( SD \) than does dividing by \( n \). However, dividing by \( n-1 \) instead of \( n \) just confuses our understanding of the standard deviation even further. For the purposes of interpretation, assume that the divisor is \( n \) so that the operation can be thought of as computing an average.

Average Absolute Deviation

If you had to devise a measure of variability, many of you would employ the average absolute deviation (AD) which is computed by forming the deviations from the mean, taking their absolute values, and computing their average. The absolute value has been applied to get rid of the negative signs that will occur. The formula for AD is

\[
AD = \frac{\sum_{i=1}^{N} |X_i - M|}{N}
\]

Notice how appealing this measure is! No squaring. No square roots. Just the direct calculation of the average absolute deviation about the mean. This is a simple average so we can understand it. Why isn’t this measure used? The answer is that even though the average absolute deviation is simple to understand and calculate, it is difficult to work with mathematically. Its distribution function is difficult to work with. The standard deviation is just the opposite. It is difficult to understand, but it can be worked with mathematically in statistical problems. Hence, we use the standard deviation, but don’t understand it!
Comparing AD and SD
Fortunately, the average absolute deviation and the standard deviation are usually close in value. Mathematically, you can show that $AD$ is always less than or equal to $SD$. A small simulation study is summarized below. It shows the relationship between $AD$ and $SD$ for data generated from various distributions.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Percent SD &gt; AD</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uniform</td>
<td>15%</td>
<td>Level</td>
</tr>
<tr>
<td>Normal</td>
<td>20%</td>
<td>Bell-Shaped</td>
</tr>
<tr>
<td>Gamma(5)</td>
<td>30%</td>
<td>Moderately Skewed Right</td>
</tr>
<tr>
<td>Gamma(5)^2</td>
<td>45%</td>
<td>Extremely Skewed Right</td>
</tr>
</tbody>
</table>

These distributions were selected for study because they represent a wide range of possibilities. The table shows that, for typical datasets, the standard deviation is from 15 to 30 percent larger than the average absolute deviation. And in the case of the normal distribution, the $SD$ is about 20% higher than $AD$.

Hence, for planning purposes, you can think of the standard deviation as an inflated version of the average absolute deviation.

Example
In out example, we can compute $AD$ for datasets A and B as follows.

Set A

$AD = (4+0+4)/3 = 8/3 = 2.667$. Note that $SD = 3.266$.

Set B

$AD = (1+0+1)/3 = 2/3 = 0.667$. Note that $SD = 0.8165$.

We see that the values are close, although not exactly the same. The degree of difference is certainly within the error that we would expect during the planning phase.
SD as the Average Difference Between Values

The above discussion and formula have pointed out that the standard deviation may be thought of as an average deviation from the mean. In this section, a second interpretation of the standard deviation will be given.

We can manipulate the formula for the sum of squared deviations to show that

$$
\sum_{i=1}^{N}(X_i - M)^2 = \frac{\sum_{i=1}^{N-1} \sum_{j=i+1}^{N} (X_i - X_j)^2}{N}
$$

This formula shows that the squared deviations from the mean are proportional to the squared deviations of each observation from every other observation. Note that the mean is not involved in the expression on the right. Think about that for a moment. What better measure of variability than one that compares each observation with every other observation?

Using the above relationship, the standard deviation may be calculated using the formula

$$
SD = \sqrt{\frac{\sum_{i=1}^{N-1} \sum_{j=i+1}^{N} (X_i - X_j)^2}{N}}
$$

Example

Consider again our simple example of sets A and B. Applying this operation to the three possible pairs of the data in set A (1, 5, 9) gives

\begin{align*}
(1-5)(1-5) &= 16 \\
(1-9)(1-9) &= 64 \\
(5-9)(5-9) &= 16
\end{align*}

The sum is 96. Dividing 96 by 3 (the number of pairs) again yields 32. Hence, the standard deviation is computed as $SD = \sqrt{96/9} = 3.266$ (which matches the previous result).

Likewise, for set B (4, 5, 6), the formula results in

\begin{align*}
(4-5)(4-5) &= 1 \\
(4-6)(4-6) &= 4 \\
(5-6)(5-6) &= 1
\end{align*}

so that $SD = \sqrt{6/9} = 0.8165$. 
Estimating the Standard Deviation

Our task is to find a rough estimate of the standard deviation. Several possible methods are available in the Standard Deviation Estimator procedure which may be loaded from the PASS-Other menu. *PASS* provides a panel that implements each of these methods for you.

**Estimate SD From A Set of Data Values (Data Tab)**

One method of estimating the standard deviation is to put in a typical set of values and calculate the standard deviation.

This window is also used when you need the standard deviation of a set of hypothesized means in an analysis of variance sample size study.

**Pros and Cons of This Method**

This method lets you experiment with several different data values. It lets you determine the influence of different data configurations on the standard deviation. In so doing, you can come up with a likely range of SD values.

However, investigators tend to pick trial numbers that are closer to the mean and more uniform than will result in practice. This results in SD’s that are underestimated. So if you use this method, you must be careful that your range of possible SD values is wide enough to be accurate.

**Example 1 - SD for a set of values**

As an example, suppose that you decide that the following values represent a typical set of data that you would anticipate for one group of individuals:

10, 12, 14, 10, 11, 10, 12, 13, 9, 13, 15, 11.

To calculate the appropriate standard deviation, do the following.

1. Load the **Standard Deviation Estimator** window and click on the **Data** tab.
2. The order that the data are entered in does not matter. However, to show the use of the Counts column, we count up the number of times each value occurs. The values and their frequency counts are then entered into the **Values** and **Counts** columns. The data entry goes as follows:
   
<table>
<thead>
<tr>
<th>Value</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>3</td>
</tr>
<tr>
<td>11</td>
<td>2</td>
</tr>
<tr>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>1</td>
</tr>
<tr>
<td>15</td>
<td>1</td>
</tr>
</tbody>
</table>

3. Check the **Use N-1 as divisor** box. (We use the N-1 divisor when estimating sigma from a set of data.)

4. Press the **Calculate Statistics** button. The standard deviation is 1.825742. We probably would round this value up to 2.0 for planning purposes.
Example 2 - SD for a set of means

In this example, we will show you how to obtain the standard deviation of a set of hypothesized means. Care must be taken that you select the correct divisor—\( N \), not \( N-1 \).

In this example, a researcher is studying the influence of a drug on heart rate. He estimates that the average heart rate of his group without the drug is 80. His experimental design will apply three different doses. The first dose is expected to lower the heart rate by 10\%, the second by 20\%, and the third by 30\%. Hence, the hypothesized means for the four groups are 80, 80(0.9) = 72, 80(0.8) = 64, and 80(0.7) = 56.

To calculate the appropriate standard deviation, do the following.

1. Load the Standard Deviation Estimator window and click on the Data tab.
2. Enter the four means into the Values column. The Counts column is left blank.
   
   \[
   \begin{array}{c}
   80 \\
   72 \\
   64 \\
   56 \\
   \end{array}
   \]
3. Make sure the Use N-1 as divisor box is not checked since we want the population standard deviation.
4. Press the Calculate Statistics button. The standard deviation of the means is 8.944272.

Estimate SD From The Standard Error (Standard Error Tab)

If the value of the standard error of the mean is available from another experiment, it may be used to estimate the standard deviation. The formula estimating the standard deviation from the standard error is

\[
SD = SE\sqrt{N}
\]

where \( N \) is the sample size.

Pros and Cons of This Method

This method is only useful when you have a standard error value available.

Example

To calculate the appropriate standard deviation when a previous study of 23 individuals had a standard error of the mean of 2.7984, do the following.

1. Load the Standard Deviation Estimator window and click on the Standard Error tab.
2. Enter 23 for \( N \).
3. Enter 2.7984 for Standard Error.
4. Press the Calculate Standard Deviation button. The standard deviation is 1.825742. We probably would round this value up to 2.0 for planning purposes.
Estimate SD From The Range (Range Tab)

There are two cases in which the range may be used to estimate the standard deviation. In the first case, the sample size and data range may be available from a previous study. In the second case, a reasonable estimate of the population range may be obtainable. This window allows you to estimate SD in both of these situations.

The basic formula for estimating the standard deviation from the range is

\[ \text{SD} = \frac{\text{Range}}{C} \]

where \( C \) is determined by the situation.

Determining \( C \)

If the data range is available from a previous study, the constant \( C \) is the median of the distribution of the range for that sample range. This distribution assumes that the data themselves are normally distributed. The median of the distribution of the range is calculated in NCSS using numerical methods. You can find it in our Probability Calculator. The calculated value of \( C \) is shown to the right of the Standard Deviation box. To use this method, leave the Population Divisor box empty.

If the a population range can be established, it may be used to estimate sigma by dividing by an appropriate constant. To determine an appropriate value of the constant, statisticians use the fact that most of the data is contained within three standard deviations of the mean—so they set \( C \) to six. However, consultants have found that for one reason (understated range) or another (population not normal) dividing by six tends to understate the standard deviation. So they divide by five or even four. Dividing by a smaller number increases the estimated standard deviation. Our recommendation is to divide by four. To use this method, enter the divisor (4, 5, or 6) in the Population Divisor box.

Pros and Cons of This Method

The range is a poor substitute for having the standard deviation. This method should be used as a ‘last resort.’

Example 1 - Previous Sample Available

To calculate an estimate of the standard deviation when a previous study of 20 animals had a minimum value of 15.3 and a maximum of 18.7, do the following.

1. Load the Standard Deviation Estimator window and click on the Range tab.
2. Enter 20 for N.
3. Enter 3.4 for Range. This is 18.7 minus 15.3.
4. Be sure that the Population Divisor box is blank.
5. Press the Calculate Standard Deviation button. The estimate of the standard deviation is 0.92243. The value of \( C \) used is 3.685916.
Example 2 - Population Range ‘Known’
To calculate an estimate of the standard deviation when the population range is known to be 150, do the following.

1. Load the Standard Deviation Estimator window and click on the Range tab.
2. Enter 150 for Range.
3. Enter 4 for Population Divisor.
4. Press the Calculate Standard Deviation button. The estimate of the standard deviation is 37.5. The value of C used is 4.

Estimate SD From Two Percentiles (Percentiles Tab)
If you are willing to assume that the population values are normally distributed (bell-shaped), you can use the values of two percentiles to estimate the standard deviation.

The basic formula for estimating the standard deviation from two percentiles is

\[
SD = \frac{X_2 - X_1}{Z\left(P_2\frac{100}{100}\right) - Z\left(P_1\frac{100}{100}\right)}
\]

where \(X_1\) and \(X_2\) are the two percentiles, \(P_1\) and \(P_2\) are the two percentages, and \(Z(P)\) is the standard normal deviate that has a tail area of \(P\) to the left.

Pros and Cons of This Method
This method works well if you have two accurate percentiles available and the underlying distribution of the data is normal.

Example
To calculate an estimate of the standard deviation when you know that the 25\(^{th}\) percentile of the population is 80.25, the 75\(^{th}\) percentile of the population is 116.38, and that the population is normally distributed, do the following.

1. Load the Standard Deviation Estimator window and click on the Percentiles tab.
2. Enter 25 for Percentage 1.
3. Enter 80.25 for Percentile Value 1.
4. Enter 75 for Percentage 2.
5. Enter 116.38 for Percentile Value 2.
6. Press the Calculate Standard Deviation button. The estimate of the standard deviation is 26.78321.
Estimate SD From The Coefficient of Variation (COV Tab)
The coefficient of variation (COV) is equal to SD divided by the mean. Hence, if you know the coefficient of variation and the mean, you can estimate SD.

Note that t-tests and the analysis of variance assume that the standard deviations are equal for all groups. If the standard deviations are proportional to their group means, you should use a data transformation (such as the square root or the logarithm) to make the standard deviations equal.

The basic formula for estimating the standard deviation from the COV is

\[ SD = \frac{COV}{Mean} \]

Pros and Cons of This Method
This method works well if you have estimates of the mean and COV.

Example
To calculate an estimate of the standard deviation when you know that the mean is 127 and the COV is 0.832, do the following.

1. Load the Standard Deviation Estimator window and click on the COV tab.
2. Enter 0.832 for COV.
3. Enter 127 for Mean.
4. Press the Calculate Standard Deviation button. The estimate of the standard deviation is 105.664.

Confidence Interval for a Sample Standard Deviation (Confidence Limits Tab)
Often, you will obtain an estimate of the standard deviation from a previous study or a pilot study. Since this estimate is based on a sample, it is important to understand its precision. This can easily be calculated since the square of the sample standard deviation follows a chi-squared distribution. This confidence interval does assume that the population you are sampling from is normally distributed.

Once a confidence interval has been obtained, it would be wise to enter both values into the appropriate place in the sample size calculations to provide a range of possible sample size values (or of statistical power).

Example
Suppose a pilot study of 10 individuals yields a standard deviation of 83.21. Calculate a 95% confidence interval for the population standard deviation using these results.

1. Load the Standard Deviation Estimator window and click on the Confidence Limits tab.
2. Enter 10 for N.
3. Enter 83.21 for Standard Deviation.
4. Enter 0.05 for Alpha.
5. Press the Calculate Confidence Limits button. The confidence limits are 57.23477 and 151.909.
Chapter 910

Odds Ratio Estimator

Introduction

This procedure calculates any one of three parameters, odds ratio, \( p_1 \), or \( p_2 \), from the other two parameters. Note that \( p_1 \) and \( p_2 \) are the proportions in groups one and two, respectively. This provides you with a tool to study the relationship between these three parameters. This procedure is most often used when planning the sample size for a test involving two proportions. The procedure may be loaded by selecting Odds Ratio Estimator from the PASS-Other menu.

When planning studies involving two proportions, two parameters, \( p_1 \) and \( p_2 \), need to be specified. At times, it may be difficult to propose a value for \( p_2 \). In these cases, it might be easier to propose a value for the odds ratio (OR).

The odds of obtaining the response of interest in group 1 are \( p_1 / (1 - p_1) \) and the odds of obtaining the response in group 2 are \( p_2 / (1 - p_2) \). The ratio of these odds, called the odds ratio, is defined as

\[
OR = \frac{p_2 / (1 - p_2)}{p_1 / (1 - p_1)} = \frac{p_2 (1 - p_1)}{p_1 (1 - p_2)}
\]

To understand better how to interpret an odds ratio, consider the following example. Suppose the proportion dying from a particular disease during the first five years is 80%. The odds of dying are thus 0.8 / 0.2 = 4.0. Suppose a treatment reduces the death rate from 80% to 60%. The odds of dying are now 0.6 / 0.4 = 1.5. The odds ratio is 4.0 / 1.5 = 2.7. That is, the odds of dying have been reduced by a factor of 2.67.

The odds ratio is reversible. In this example, suppose we talk in terms of surviving instead of dying. The odds of the two groups are now 0.2 / 0.8 = 0.25 and 0.4 / 0.6 = 0.67. The odds ratio is 0.67 / 0.25 = 2.67. The odds of surviving have increased by a factor of 2.67.

In some situations, it may be easier to define a meaningful treatment effect in terms of the odds ratio. That is, it might be meaningful to say that a certain treatment increases the odds of survival by 50% (\( OR = 1.5 \)) or by 200% (\( OR = 2.0 \)). If this is the case, a value for \( p_2 \) can be calculated from \( p_1 \) and \( OR \) by solving the above equation for \( p_2 \) to find that

\[
p_2 = \frac{p_1 (OR)}{1 - p_1 + p_1 (OR)}
\]
Hence, given a value for \( p_1 \) and \( OR \), you can calculate an appropriate value for \( p_2 \).

**Odds Ratio Tab**

This window lets you enter values for two of the three parameters used to form an odds ratio and calculate the remaining parameter.

**Example 1 - Solving for P1**

Suppose you know that \( p_2 = 0.8 \) and that \( OR = 4 \) and you want to find the corresponding value of \( p_1 \).

1. Load the Odds Ratio Estimator procedure by selecting it from the PASS-Other menu.
2. Set P2 equal to 0.8.
4. Press the Calculate P1 button.
5. Read the result in the P1 box. The result is 0.5

**Example 2 - Solving for P2**

Suppose you know that \( p_1 = 0.4 \) and that \( OR = 1.5 \) and you want to find the corresponding value of \( p_2 \).

1. Load the Odds Ratio Estimator procedure by selecting it from the PASS-Other menu.
2. Set P1 equal to 0.4.
3. Set Odds Ratio equal to 1.5.
4. Press the Calculate P2 button.
5. Read the result in the P2 box. The result is 0.5.

**Example 3 - Solving for Odds Ratio**

Suppose you know that \( p_1 = 0.4 \) and that \( p_2 = 0.8 \) and you want to find the corresponding value of the odds ratio.

1. Load the Odds Ratio Estimator procedure by selecting it from the PASS-Other menu.
2. Set P1 equal to 0.4.
3. Set P2 equal to 0.8.
4. Press the Calculate Odds Ratio button.
5. Read the result in the Odds Ratio box. The result is 6.
References

AIAG (Automotive Industry Action Group). 1995. Measurement Systems Analysis. This booklet was developed by Chrysler/Ford/GM Supplier Quality Requirements Task Force. It gives a detailed discussion of how to design and analyze an R&R study. The book may be obtained from ASQC or directly from AIAG by calling 801-358-3570.

Albert, A. and Harris, E. 1987. Multivariate Interpretation of Clinical Laboratory Data. Marcel Dekker, New York, New York. This book is devoted to a discussion of how to apply multinomial logistic regression to medical diagnosis. It contains the algorithm that is the basis of our multinomial logistic regression routine.

Allen, D. and Cady, F. 1982. Analyzing Experimental Data by Regression. Wadsworth. Belmont, Calif. This book works completely through several examples. It is very useful to those who want to see complete analyses of complex data.

Altman, Douglas. 1991. Practical Statistics for Medical Research. Chapman & Hall. New York, NY. This book provides an introductory discussion of many statistical techniques that are used in medical research. It is the only book we found that discussed ROC curves.

Baker, Frank. 1992. *Item Response Theory*. Marcel Dekker. New York. This book contains a current overview of IRT. It goes through the details, providing both formulas and computer code. It is not light reading, but it will provide you with much of what you need if you are attempting to use this technique.

Box, G.E.P. and Jenkins, G.M. 1976. *Time Series Analysis - Forecasting and Control*. Holden-Day.: San Francisco, California. This is the landmark book on ARIMA time series analysis. Most of the material in chapters 6 - 9 of this manual comes from this work.

Hsieh, F.Y. 1989. “Sample Size Tables for Logistic Regression,” *Statistics in Medicine*, Volume 8, pages 795-802. This is the article that was the basis for the sample size calculations in logistic regression in PASS 6.0. It has been superceded by the 1998 article.

**Jackson, J.E.** 1991. *A User's Guide To Principal Components.* John Wiley & Sons. New York. This is a great book to learn about PCA from. It provides several examples and treats everything at a level that is easy to understand.

**James, Mike.** 1985. *Classification Algorithms.* John Wiley & Sons. New York. This is a great text on the application of discriminant analysis. It includes a simple, easy-to-understand, theoretical development as well as discussions of the application of discriminant analysis.

**Kaufman, L. and Rousseuw, P.J.** 1990. *Finding Groups in Data.* John Wiley. New York. This book gives an excellent introduction to cluster analysis. It treats the forming of the distance matrix and several different types of cluster methods, including fuzzy. All this is done at an elementary level so that users at all levels can gain from it.

Kruskal, J. 1964. “Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis.” *Psychometrika* 29, pages 1-27, 115-129. This article presents the algorithm on which the non-metric algorithm used in NCSS is based.

Kruskal, J. and Wish, M. 1978. *Multidimensional Scaling*. Sage Publications. Beverly Hills, CA. This is a well-written monograph by two of the early pioneers of MDS. We suggest it to all serious students of MDS.

Lachenbruch, P.A. 1975. *Discriminant Analysis*. Hafner Press. New York. This is an in-depth treatment of the subject. It covers a lot of territory, but has few examples.

Lachin, John M. 2000. *Biostatistical Methods*. John Wiley & Sons. New York. This is a graduate-level methods book that deals with statistical methods that are of interest to biostatisticians such as odds ratios, relative risks, regression analysis, case-control studies, and so on.

Lawson, John. 1987. *Basic Industrial Experimental Design Strategies*. Center for Statistical Research at Brigham Young University. Provo, Utah. 84602. This is a manuscript used by Dr. Lawson in courses and workshops that he provides to industrial engineers. It is the basis for many of our experimental design procedures.

Lipsey, Mark W. 1990. Design Sensitivity Statistical Power for Experimental Research, Sage Publications, 2111 West Hillcrest Drive, Newbury Park, CA. 91320. This is an excellent introduction to power analysis.

Makridakis, S. and Wheelwright, S.C. 1978. Iterative Forecasting. Holden-Day.: San Francisco, California. This is a very good book for the layman since it includes several detailed examples. It is written for a person with a minimum amount of mathematical background.

Mather, Paul. 1976. *Computational Methods of Multivariate Analysis in Physical Geography*. John Wiley & Sons. This is a great book for getting the details on several multivariate procedures. It was written for non-statisticians. It is especially useful in its presentation of cluster analysis. Unfortunately, it is out-of-print. You will have to look for it in a university library (it is worth the hunt).

Mosteller, F. and Tukey, J.W. 1977. *Data Analysis and Regression*. Addison-Wesley. Menlo Park, California. This book should be read by all serious users of regression analysis. Although the terminology is a little different, this book will give you a fresh look at the whole subject.

Motulsky, Harvey. 1995. *Intuitive Biostatistics*. Oxford University Press. New York, New York. This is a wonderful book for those who want to understand the basic concepts of statistical testing. The author presents a very readable coverage of the most popular biostatistics tests. If you have forgotten how to interpret the various statistical tests, get this book!

Myers, R.H. 1990. Classical and Modern Regression with Applications. PWS-Kent Publishing Company. Boston, Massachusetts. This is one of the bibles on the topic of regression analysis.

Orloci, L. & Kenkel, N. 1985. *Introduction to Data Analysis*. International Co-operative Publishing House. Fairland, Maryland. This book was written for ecologists. It contains samples and BASIC programs of many statistical procedures. It has one brief chapter on MDS, and it includes a non-metric MDS algorithm.

Ott, L. 1984. *An Introduction to Statistical Methods and Data Analysis, Second Edition*. Wadsworth. Belmont, Calif. This is a complete methods text. Regression analysis is the focus of five or six chapters. It stresses the interpretation of the statistics rather than the calculation, hence it provides a good companion to a statistical program like ours.

Pregibon, Daryl. 1981. “Logistic Regression Diagnostics.” *Annals of Statistics*, Volume 9, Pages 705-725. This article details the extensions of the usual regression diagnostics to the case of logistic regression. These results were extended to multiple-group logistic regression in Lesaffre and Albert (1989).

Prihoda, Tom. 1983. “Convenient Power Analysis For Complex Analysis of Variance Models.” *Poster Session of the American Statistical Association Joint Statistical Meetings*, August 15-18, 1983, Toronto, Canada. Tom is currently at the University of Texas Health Science Center. This article includes FORTRAN code for performing power analysis.
Ramsey, Philip H. 1978 “Power Differences Between Pairwise Multiple Comparisons,” *JASA*, vol. 73, no. 363, pages 479-485.

Rencher, Alvin C. 1998. *Multivariate Statistical Inference and Applications.* John Wiley. New York, New York. This book provides a comprehensive mixture of theoretical and applied results in multivariate analysis. My evaluation may be biased since Al Rencher took me fishing when I was his student.

Ryan, Thomas P. 1997. *Modern Regression Methods.* John Wiley & Sons. New York. This is a comprehensive treatment of regression analysis. The author often deals with practical issues that are left out of other texts.

Shuster, Jonathan J. 1990. *CRC Handbook of Sample Size Guidelines for Clinical Trials*. CRC Press, Boca Raton, Florida. This is an expensive book ($300) of tables for running log-rank tests. It is well documented, but at this price it better be.

Tabachnick, B. and Fidell, L. 1989. *Using Multivariate Statistics*. Harper Collins. 10 East 53d Street, NY, NY 10022. This is an extremely useful text on multivariate techniques. It presents computer printouts and discussion from several popular programs. It provides checklists for each procedure as well as sample written reports. I strongly encourage you to obtain this book!

Therneau, T.M. and Grambsch, P.M. 2000. *Modeling Survival Data*. Springer: New York, New York. A the time of the writing of the Cox regression procedure, this book provides a thorough, up-to-date discussion of this procedure as well as many extensions to it. Recommended, especially to those with at least a masters in statistics.

Torgenson, W.S. 1952. “Multidimensional scaling. I. Theory and method.” *Psychometrika* 17, 401-419. This is one of the first articles on MDS. There have been many advances, but this article presents many insights into the application of the technique. It describes the algorithm on which the metric solution used in this program is based.

Welch, B.L. 1938. "The significance of the difference between two means when the population variances are unequal." *Biometrika*, 29, 350-362.

Wilson, E.B.. 1927. “Probable Inference, the Law of Succession, and Statistical Inference,” *Journal of the American Statistical Association*, Volume 22, pages 209-212. This article discusses the ‘score’ method that has become popular when dealing with proportions.

Note that most index entries are of the form “chapter-page”. If no chapter is given, the entry refers to the introductory chapters. A list of chapters is given in the Table of Contents.
